RXF

ROTARY SCREW COMPRESSOR UNITS

MODELS 12 – 101

THIS MANUAL CONTAINS RIGGING, ASSEMBLY, START-UP, AND MAINTENANCE INSTRUCTIONS. READ THOROUGHLY BEFORE BEGINNING INSTALLATION. FAILURE TO FOLLOW THESE INSTRUCTIONS MAY RESULT IN PERSONAL INJURY OR DEATH, DAMAGE TO THE UNIT, OR IMPROPER OPERATION.

General Information

PREFACE

This manual has been prepared to acquaint the owner and service person with the INSTALLATION, OPERATION, and MAINTENANCE procedures as recommended by Frick for RXF Rotary Screw Compressor Units.

It is most important that these units be properly applied to an adequately controlled refrigeration system. Your authorized Frick representative should be consulted for expert guidance in this determination.

Proper performance and continued satisfaction with these units is dependent upon:

CORRECT INSTALLATION
PROPER OPERATION
REGULAR, SYSTEMATIC PLANNED MAINTENANCE

To ensure correct installation and application, the equipment must be properly selected and connected to a properly designed and installed system. The Engineering plans, piping layouts, etc. must be detailed in accordance with the best practices and local codes, such as those outlined in ASHRAE literature.

A refrigeration compressor is a VAPOR PUMP. To be certain that it is not being subjected to liquid refrigerant carryover, it is necessary that refrigerant controls are carefully selected and in good operating condition; the piping is properly sized and traps, if necessary, are correctly arranged; the suction line has an accumulator or slugging protection; that load surges are known and provisions made for control; operating cycles and defrosting periods are reasonable; oil return is controlled; and that high side condenser units control head pressures and temperatures are within system and compressor design limits.

It is recommended that the entering vapor temperature to the compressor be superheated to 10°F above the refrigerant saturation temperature to ensure that all refrigerant at the compressor suction is in the vapor state.

DESIGN LIMITATIONS

The compressor units are designed for operation within the pressure and temperature limits as shown in Frick Publication 070.410-SED.

JOB INSPECTION

Immediately upon arrival examine all crates, boxes, and exposed compressor and component surfaces for damage. Unpack all items and check against shipping lists for any possible shortage. Examine all items for damage in transit.

TRANSIT DAMAGE CLAIMS

All claims must be made by consignee. This is an ICC requirement. Request immediate inspection by the agent of the carrier and be sure the proper claim forms are executed.

Contact Johnson Controls-Frick, Sales Administration Department, in Waynesboro, PA to report damage or shortage claims.

UNIT IDENTIFICATION

Each compressor unit has two identification data plates. The unit data plate containing unit model, serial number and Frick sales order number is mounted on the control panel support bracket. The compressor data plate containing compressor model and serial number is mounted on the compressor body.

NOTICE

When inquiring about the compressor or unit, or ordering repair parts, provide the MODEL, SERIAL, and FRICK SALES ORDER NUMBERS from these data plates.

SAFETY PRECAUTION DEFINITIONS

⚠️ DANGER
Indicates an imminently hazardous situation which, if not avoided, will result in death or serious injury.

⚠️ WARNING
Indicates a potentially hazardous situation or practice which, if not avoided, will result in death or serious injury.

⚠️ CAUTION
Indicates a potentially hazardous situation or practice which, if not avoided, will result in damage to equipment and/or minor injury.

⚠️ NOTICE
Indicates an operating procedure, practice, etc., or portion thereof which is essential to highlight.
COMPRESSOR IDENTIFICATION

Rotary screw compressor serial numbers are defined by the following information:
EXAMPLE: 10240A9000015Z

Installation

FOUNDATION

NOTICE

Allow space for servicing the unit per factory drawings.

The first requirement of the compressor foundation is that it must be able to support the weight of the compressor package including coolers, oil, and refrigerant charge. Screw compressors are capable of converting large quantities of shaft power into gas compression in a relatively small space and a mass is required to effectively dampen these relatively high frequency vibrations.

Firmly anchoring the compressor package to a suitable foundation by proper application of grout and elimination of piping stress imposed on the compressor is the best insurance for a trouble free installation. Use only the certified general arrangement drawings from Frick® to determine the mounting foot locations and to allow for recommended clearances around the unit for ease of operation and servicing. Foundations must be in compliance with local building codes and materials should be of industrial quality.

The floor shall be a minimum of 6 inches of reinforced concrete and housekeeping pads are recommended. Anchor bolts are required to firmly tie the unit to the floor. Once the unit is rigged into place (See HANDLING and MOVING), the feet must then be shimmed in order to level the unit. The shims should be placed to position the feet roughly one inch above the housekeeping pad to allow room for grouting. An expansion-type epoxy grout must be worked under all areas of the base with no voids and be allowed to settle with a slight outward slope so oil and water can run off of the base.

When installing on a steel base, the following guidelines should be implemented to properly design the system base:

1. Use I-beams in the skid where the screw compressor will be attached to the system base. They shall run parallel to the package feet and support the feet for their full length.
2. The compressor unit feet shall be continuously welded to the system base at all points of contact.
3. The compressor unit shall not be mounted on vibration isolators in order to hold down package vibration levels.
4. The customer’s foundation for the system base shall fully support the system base under all areas, but most certainly under the I-beams that support the compressor package.

When installing on the upper floors of buildings, extra precautions should be taken to prevent normal package vibration from being transferred to the building structure. It may be necessary to use rubber or spring isolators, or a combination of both, to prevent the transmission of compressor vibration directly to the structure. However, this may increase package vibration levels because the compressor is not in contact with any damping mass. The mounting and support of suction and discharge lines is also very important. Rubber or spring pipe supports may be required to avoid exciting the building structure at any pipe supports close to the compressor package. It is best to employ a vibration expert in the design of a proper mounting arrangement.

In any screw compressor installation, suction and discharge lines shall be supported in pipe hangers (preferably within 2 feet of vertical pipe run) so that the lines won’t move if disconnected from the compressor. See table for Allowable Flange Loads.

</table>

Proper foundations and proper installation methods are vital; and even then, sound attenuation or noise curtains may be required to reduce noise to desired levels.

For more detailed information on Screw Compressor Foundations, please request Frick publication 070.210-IB.

#### HANDLING and MOVING

**WARNING**

This screw compressor package may be top-heavy. Use caution in rigging and handling.

RxF 12–50 units can be moved with a forklift or with rigging and a crane. The recommended method is to insert lengths of 2" pipe through the base tubing (see Figure 1 below).

**CAUTION**

Spreader bars should be used on both the length and width of the package to prevent bending oil lines and damage to the package. CAUTION must also be used in locating the lifting ring. Appropriate adjustment in the lifting point should be made to compensate for motor weight. Adjustment of the lifting point must also be made for any additions to the standard package such as an external oil cooler, etc., as the center of balance will be affected.

![Figure 1 - RXF 12–50](image-url)
The unit can be moved with a forklift by forking through the base tubing. NEVER MOVE THE UNIT BY PUSHING OR FORKING AGAINST THE SEPARATOR SHELL OR ITS MOUNTING SUPPORTS.

RXF 58 – 101 units can be moved with rigging, using a crane or forklift by hooking into three lifting points on the oil separator. See Figure 2.

CAUTION

Spread bars may be required on both the length and width of the package to prevent bending oil lines and damage to the package. CAUTION must also be used in locating the lifting ring. Appropriate adjustment in the lifting point should be made to compensate for motor weight. Adjustment of the lifting point must also be made for any additions to the standard package such as an external oil cooler, etc., as the center of balance will be affected.

Figure 2 - RXF 58 – 101

The unit can be moved with a forklift by forking under the wooden skid (if provided), or it can be skidded into place with pinch bars by pushing against the skid. NEVER MOVE THE UNIT BY PUSHING OR FORKING AGAINST THE SEPARATOR SHELL OR ITS MOUNTING SUPPORTS.

SKID REMOVAL

CAUTION

This screw compressor package may be top-heavy. Use caution to prevent unit from turning over.

If the unit is rigged into place, the wooden skid can be removed by taking off the nuts and bolts that are fastening the unit mounting supports to the skid before lowering the unit onto the mounting surface.

If the unit is skidded into place, remove the cross members from the skid and remove the nuts anchoring the unit to the skid. Using a 10-ton jack under the separator, raise the unit at the compressor end until it clears the two mounting bolts. Spread the skid to clear the unit mounting support, then lower the unit to the surface. Repeat procedure on opposite end.

COMPRESSOR/MOTOR COUPLINGS

RXF units are arranged for direct motor drive and include a flexible drive coupling to connect the compressor to the motor.

CH COUPLING

The T. B. Woods Elastomeric Type CH Coupling is used in most applications. This coupling consists of two drive hubs and a gear-type Hytrel, EPM, or neoprene drive spacer. The split hub is clamped to the shaft by tightening the clamp screws. Torque is transmitted from the motor through the elastomeric gear which floats freely between the hubs. Because of the use of the motor/compressor adapter housing on the RXF, no field alignment is necessary.

WARNING

It is mandatory that the coupling center be removed and the direction of motor rotation be confirmed before running the compressor. Proper rotation of the compressor shaft is clockwise looking at the end of the compressor shaft. Failure to follow this step could result in backward compressor rotation which can cause compressor failure or explosion of the suction housing.

1. Inspect the shaft of the motor and compressor to ensure that no nicks, grease, or foreign matter is present.
2. Inspect the bores in the coupling hubs to make sure they are free of burrs, dirt, and grit.
3. Check that the keys fit the hubs and shafts properly.
4. Slide one hub onto each shaft as far as possible. It may be necessary to use a screwdriver as a wedge in the slot to open the bore before the hubs will slide on the shafts.
5. Hold the elastomeric gear between the hubs and slide both hubs onto the gear to fully engage the mating teeth. Center the gear and hub assembly so there is equal engagement on both shafts. Adjust the space between hubs as specified in the CH Coupling Data Table below. SEE NOTICE:

5. Hold the elastomeric gear between the hubs and slide both hubs onto the gear to fully engage the mating teeth. Center the gear and hub assembly so there is equal engagement on both shafts. Adjust the space between hubs as specified in the CH Coupling Data Table below. SEE NOTICE:
NOTICE
The center section will be a little loose between the hubs. This allows for growth during operation.

6. Torque the clamping bolts in both hubs to the torque value given in the CH Data Table. **DO NOT USE ANY LUBRICANT ON THESE BOLTS.**

**HOLDING CHARGE and STORAGE**

Each compressor unit is pressure and leak tested at the Johnson Controls-Frick factory and then thoroughly evacuated and charged with dry nitrogen to ensure the integrity of the unit during shipping and short term storage prior to installation.

**CAUTION**
Care must be taken when entering the unit to ensure that the nitrogen charge is safely released.

**WARNING**
Holding charge shipping gauges on separator and external oil cooler are rated for 30 PSIG and are for checking the shipping charge only. They must be removed before pressure testing the system and before charging the system with refrigerant. Failure to remove these gauges may result in catastrophic failure of the gauge and uncontrolled release of refrigerant resulting in serious injury or death.

All units must be kept in a clean, dry location to prevent corrosion damage. Reasonable consideration must be given to proper care for the solid-state components of the microprocessor.

Units which will be stored for more than two months must have the nitrogen charge checked periodically. Contact Johnson Controls-Frick for long term storage procedure.

**COMPRESSOR OIL**

**WARNING**
**DO NOT MIX OILS** of different brands, manufacturers, or types. Mixing of oils may cause excessive oil foaming, nuisance oil level cutouts, oil pressure loss, gas or oil leakage and catastrophic compressor failure.

**NOTICE**
The oil charge shipped with the unit is the best suited lubricant for the conditions specified at the time of purchase. If there is any doubt due to the refrigerant, operating pressures, or temperatures; refer to Frick publication 160.802-SPC for guidance.

**OIL CHARGE**
The normal charging level is midway in the top sight glass located midway along the oil separator shell. Normal operating level is between the top sight glass and bottom sight glass. Oil charge quantities are as follows:

<table>
<thead>
<tr>
<th>RXF MODEL</th>
<th>BASIC CHARGE (gallon)</th>

</tr>
</tbody>
</table>

Add oil by attaching the end of a suitable pressure type hose to the oil drain valve (see Figure 3), located under the oil separator. Using a pressure-type pump and the recommended Frick® oil, open the drain valve and pump oil into the separator.

**NOTICE**
Evacuation of the oil separator will assist the flow of oil into the unit. Also, fill slowly because oil will fill up in the separator faster than it shows in the sight glass.

Oil distillers and similar equipment which trap oil must be filled prior to unit operation to normal design outlet levels. The same pump used to charge the unit may be used for filling these auxiliary oil reservoirs.

The sight glass located near the bottom of the separator shell at the discharge end should remain empty when the unit is in operation. The presence of oil in this end of the vessel during operation indicates liquid carryover or malfunction of the oil return.

**Figure 3 - Oil Drain Valve**

**OIL HEATER**

Standard units are equipped with 500 watt oil heaters, which provide sufficient heat to maintain the oil temperature for most indoor applications during shutdown cycles and to permit safe start-up. RXF 12–50 use one heater while models 58–101 use two. Should additional heating capacity be required because of an unusual environmental condition, contact Johnson Controls-Frick. The heater is energized only when the unit is not in operation.

**WARNING**
Do not energize the heater when there is no oil in the unit, otherwise the heater will burn out. The oil heater will be energized whenever 120 volt control power is applied to the unit and the compressor is not running, unless the 16 amp circuit breaker in micro enclosure is turned off (or 15 amp fuse (1FU) in the Plus panel is removed).
OIL FILTER(S)

NOTICE
Use of filter elements other than Frick may cause warranty claim to be denied.

The oil filter(s) and coalescer filter element(s) shipped with the unit are best suited to ensure proper filtration and operation of the system.

SUCTION ISOLATION VALVE MOUNTING

The suction isolation valve is shipped loose from the factory, so it can be installed at various positions within the suction line piping to the compressor. **DO NOT INSTALL** the valve at the compressor suction with flow against the cone/button (see Figure 4 TOP). When the isolation valve is installed in this position, uneven flow is generated across the suction check valve which is mounted at the inlet to the compressor. This uneven flow causes the disks in the check valve to strike against the stop pin, and eventually damage the internals of the check valve. If the isolation valve is mounted at the compressor suction, **DO INSTALL** with flow across the cone/button (see Figure 4 BOTTOM). Please design your system piping accordingly.

**CAUTION**

After removing the suction sealing disc, confirm that the check valve hinge pin is in the vertical position! If the hinge pin is not in a vertical position, then failure of the check valve may occur.

THERMOSYPHON OIL COOLING

**EQUIPMENT:** The basic equipment required for a thermosyphon system consists of:

1. A source of liquid refrigerant at condensing pressure and temperature located in close proximity to the unit to minimize piping pressure drop.

The liquid level in the refrigerant source must be 6 to 8 feet above the center of the oil cooler.

2. A shell and tube or plate-type oil cooler with a minimum 300 psi design working pressure on both the oil and refrigerant sides.

Due to the many variations in refrigeration system design and physical layout, several systems for assuring the above two criteria are possible.

**INSTALLATION:** The plate-type thermosyphon oil cooler with oil side piping and a thermostatically controlled mixing valve are factory mounted and piped. See Figure 5.

**Figure 5 - Thermosyphon Oil-Cooled System**

1. Thermosyphon oil cooler is supplied with oil side piped to the compressor unit and socket weld ends supplied on the refrigerant side.

2. A refrigerant-side safety valve is required when refrigerant isolation valves are installed between the cooler and thermosyphon receiver. If no valves are used between the cooler and thermosyphon receiver, the safety valve on the thermosyphon receiver must be sized to handle the volume of both vessels. Then, the safety valve on the cooler vent (liquid refrigerant side) can be eliminated.

3. System receiver must be mounted below thermosyphon receiver level in this arrangement.

4. The refrigerant source, thermosyphon or system receiver, should be in close proximity to the unit to minimize piping pressure drop.

5. The liquid level in the refrigerant source must not be less than 6 feet above the center of the oil cooler.

6. An angle valve should be installed in the piping before the thermosyphon oil cooler to balance the thermosyphon system. Sight glasses should also be installed at the TSOC inlet and outlet to aid in troubleshooting. The factory-mounted plate-type thermosyphon oil cooler requires a refrigerant-side drain valve to be provided and installed by the customer.

The component and piping arrangement shown in Figure 5 is intended only to illustrate the operating principles of thermosyphon oil cooling. Other component layouts may be better suited to a specific installation. Refer to publication 070.900-E for additional information on Thermosyphon Oil Cooling.
WATER-COOLED OIL COOLING

The plate-type water-cooled oil cooler is mounted on the unit complete with all oil piping. The customer must supply adequate water to the oil cooler.

Johnson Controls-Frick recommends a closed-loop system for the waterside of the oil cooler. Careful attention to water treatment is essential to ensure adequate life of the cooler if cooling tower water is used. It is imperative that the condition of cooling water and closed-loop fluids be analyzed regularly and as necessary and maintained at a pH of 7.4, but not less than 6.0 for proper heat exchanger life. After initial start-up of the compressor package, the strainer at the inlet of the oil cooler should be cleaned several times in the first 24 hours of operation.

In some applications, the plate-type oil cooler may be subjected to severe water conditions, including high temperature and/or hard water conditions. This causes accelerated scaling rates which will penalize the performance of the heat exchanger. A chemical cleaning process will extend the life of the heat exchanger. It is important to establish regular cleaning schedules.

Cleaning: A 3% solution of Phosphoric or Oxalic Acid is recommended. Other cleaning solutions can be obtained from your local distributor, but they must be suitable for stainless steel. The oil cooler may be cleaned in place by back flushing with recommended solution for approximately 30 minutes. After back flushing, rinse the heat exchanger with fresh water to remove any remaining cleaning solution.

FIELD WELDING INSTRUCTIONS FOR TSOC AND WCOC:
The heat exchanger body is constructed in stainless steel, while the stub connections are carbon steel. The highly polished stub connections can give the appearance of stainless steel. The following are requirements for welding to the socket weld fittings on Plate heat exchangers:

1. Use a heat-sink paste around the base of the connection. These are available from a number of suppliers of welding materials.

CAUTION

Heat-sink paste must be applied around the base of the connection prior to welding. See Figure 6.

2. Two-pass welding is required; stagger start/stop region; welding procedure in accordance with ASME Section 9.

3. If possible use gas protection, when welding, to avoid oxidation of the surface. As it is rarely possible to clean the root side of the weld by grinding or brushing to remove the root oxide, it is optimal to use root gas.

4. Welding should occur in two segments, from 6:00 to 12:00. The maximum intersegment temperature should be 350°F. Temperature should be verified with temperature indicating crayon or equivalent.

5. The fitting may be cooled with forced air to reduce the temperature of the fitting to 350°F or lower, prior to welding the second segment.

The maximum connection static forces and moments for Alfa Nova heat exchangers are listed in the following table. Keep these values in mind when designing your system. It is also recommended to minimize connection loads when designing piping systems. Also see Figure 7.

* 100 ft. liquid line. For longer runs, increase line size accordingly.

CONDITIONS: High Stage at 0°F Evap, and 95°F Cond, 10°F suction superheat; Booster at -40°F Evap, 95°F Cond, 20°F
Intermediate, and 10°F suction superheat; R-507 unloaded slide valve.

High-stage compressor units may be supplied with single-port (low Vi, side, or closed thread) or dual-port (low Vi and high Vi), liquid injection oil cooling. Single port will be furnished for low compression ratio operation and dual port for high compression ratio operation. Booster compressor units use single-port (High Vi), liquid injection oil cooling due to the typically lower compression ratios.

The control system on high-stage units with dual-port, liquid injection oil cooling switches the liquid refrigerant supply to the high port when the compressor is operating at higher compression ratios (3.5 Vi and above) for best efficiency. Where low compression ratios (low condensing pressures) are anticipated, thermosyphon or water-cooled oil cooling should be used.

**CAUTION**

It is imperative that an uninterrupted high-pressure liquid refrigerant be provided to the injection system at all times. Two items of EXTREME IMPORTANCE are the design of the receiver/liquid injection supply and the size of the liquid line. It is recommended that the receiver be oversized sufficiently to retain a 5-minute supply of refrigerant for oil cooling. The evaporator supply must be secondary to this consideration. Failure to follow these requirements causes wire draw which can result in damage to the expansion valve, loss of oil cooling, and intermittent oil cooling. One method of accomplishing this is described below.

**DUAL DIP TUBE METHOD**

The dual dip tube method uses two dip tubes in the receiver. The liquid injection tube is below the evaporator tube to assure continued oil cooling when the receiver level is low. See Figure 8.

**ECONOMIZER - HIGH STAGE (OPTIONAL)**

The economizer option provides an increase in system capacity and efficiency by subcooling liquid from the condenser through a heat exchanger or flash tank before it goes to the evaporator. The subcooling is provided by flashing liquid in the economizer cooler to an intermediate pressure level. The intermediate pressure is provided by a port located part way down the compression process on the screw compressor.

As the screw compressor unloads, the economizer port will drop in pressure level, eventually being fully open to suction. Because of this, an output from the microprocessor is generally used to turn off the supply of flashing liquid on a shell and coil or DX economizer when the capacity falls below approximately 60%-70% (85%-90% slide valve position). This is done to improve compressor operating efficiency. Please note however that shell and coil and DX economizers can be used at low compressor capacities in cases where efficiency is not as important as ensuring that the liquid supply is subcooled. In such cases, the economizer liquid solenoid can be left open whenever the compressor is running.

Due to the tendency of the port pressure to fall with decreasing compressor capacity, a back-pressure regulator valve (BPR) is generally required on a Flash Economizer System (Figure 11) in order to maintain some preset pressure difference between the subcooled liquid in the flash vessel and the evaporators. If the back-pressure regulator valve is not used on a flash economizer, it is possible that no pressure difference will exist to drive liquid from the flash vessel to the evaporators, since the flash vessel will be at suction pressure. In cases where wide swings in pressure are anticipated in the flash economizer vessel, it may be necessary to add an outlet pressure regulator to the flash vessel outlet to avoid overpressurizing the economizer port, which could result in motor overload. Example: A system feeding liquid to the flash vessel in batches.

The recommended economizer systems are shown in Figures 9 – 12. Notice that in all systems there must be a strainer and a check valve between the economizer vessel and the economizer port on the compressor. The strainer prevents dirt from passing into the compressor and the check valve prevents oil from flowing from the compressor unit to the economizer vessel during shutdown.

**CAUTION**

Other than the isolation valve needed for strainer cleaning, it is essential that the strainer be the last device in the economizer line before the compressor. The strainer must be strong enough to handle the gas pulsations from the compressor. Johnson Controls-Frick recommends an R/S or Hansen strainer. Also, piston-type check valves are recommended for installation in the economizer line, as opposed to disc-type check valves. The latter are more prone to gas-pulsation-induced failure. The isolation and check valves and strainer should be located as closely as possible to the compressor, preferably within a few feet.

**Figure 8**

**ECONOMIZER - HIGH STAGE (OPTIONAL)**

For refrigeration plants employing multiple compressors on a common economizing vessel, regardless of economizer type, each compressor must have a back-pressure regulating valve in order to balance the economizer load, or gas flow, between compressors. The problem of balancing load...
becomes most important when one or more compressors run at partial load, exposing the economizer port to suction pressure. In the case of a flash vessel, there is no need for the redundancy of a back-pressure regulating valve on the vessel and each of the multiple compressors. Omit the BPR valve on the flash economizer vessel and use one on each compressor, as shown in Figure 12.

Figure 11 - Flash Economizer System

Figure 12 - Multiple Compressor Flash Economizer System

ELECTRICAL

NOTICE

Before beginning electrical installation, read the instructions in the section "Proper Installation of Electronic Equipment" at the back of this manual.

RXF units are supplied with a Quantum™HD control system. Care must be taken that the controls are not exposed to physical damage during handling, storage, and installation. The single-box control door must be kept tightly closed to prevent moisture and foreign matter from entry.

WARNING

Customer connections are made in the Quantum™HD control panel* mounted on the unit. The electrical enclosures should be kept tightly closed whenever work is not being done inside. * Or starter panel (if provided).

VOLTAGE PROTECTION

NOTICE

Johnson Controls-Frick® does not advise nor support the use of UPS power systems in front of the Quantum™HD panel.

With a UPS power system providing shutdown protection for the Quantum™HD, the panel may not see the loss of the 3-phase voltage on the motor because the UPS could prevent the motor starter contactor from dropping out. With the starter contactor still energized, the compressor auxiliary will continue to feed an “Okay” signal to the panel. This will allow the motor to be subjected to a fault condition on the 3-phase bus. Some fault scenarios are:

1. The 3-phase bus has power “on” and “off” in a continuous cyclic manner which may cause the motor to overheat due to repeated excessive in-rush currents.
2. Motor cycling may damage the coupling or cause other mechanical damage due to the repeated high torque motor “bumps”.
3. Prolonged low voltage may cause the motor to stall and overheat before the motor contactor is manually turned off.

Under normal conditions, the loss of 3-phase power will shut down the Quantum™HD panel, and it will restart upon power return. If the panel was in:

• Auto – Compressor motor will return to running as programmed.
• Remote – The external controller would reinitialize the panel and proceed to run as required.
• Manual – The compressor will have to be restarted manually after the 3-phase bus fault has been cleared.

If the local power distribution system is unstable or prone to problems, there are other recommendations to satisfy these problems. If power spikes or low or high line voltages are the problem, then we recommend the use of a Sola® constant voltage (CV) transformer with a line suppression feature. If a phase loss occurs, then you will typically get a high motor amp shutdown. If problems continue to exist, then an examination of the plant’s power factor may be in order.

Unless careful design failure analysis is considered in the implementation of power systems, the alternative solutions provide a safer and less expensive implementation. In either case, only one Sola® may be used per compressor. Each compressor needs to be individually isolated from each other through a dedicated control transformer. Sharing a common control power source is an invitation for ground loops and the subsequent unexplainable problems.
**MOTOR STARTER PACKAGE**

**CAUTION**

When starting at full voltage or across-the-line, a shunting device must be installed or the Analog I/O board in the Quantum™HD panel may be severely damaged at start-up. See Figure 13.

Motor starter and interlock wiring requirements are shown in the diagram, Figure 12. All of the equipment shown is supplied by the installer unless a starter package is purchased separately from Frick. Starter packages should consist of:

1. The compressor motor starter of the specified horsepower and voltage for the starting method specified (across-the-line, autotransformer, wye-delta or solid-state).

2. If specified, the starter package can be supplied as a combination starter with circuit breaker disconnect. However, the motor overcurrent protection/disconnection device can be applied by others, usually as a part of an electrical power distribution board.

3. A 3.0 KVA control power transformer (CPT) to supply 120 volt control power to the control system and separator oil heaters is included. If environmental conditions require more than 2000 watts of heat, an appropriately oversized control transformer will be required.

4. One normally open compressor motor starter auxiliary contact should be supplied and wired as shown on the starter package wiring diagram. In addition, the compressor starter coil and the CPT secondaries should be wired as shown on the starter package wiring diagram, Figure 13.

5. The compressor motor Current Transformer (CT) can be installed on any one phase of the compressor leads.

**NOTICE**

If starting methods other than across-the-line are desired, a motor/compressor torque analysis must be done to ensure sufficient starting torque is available. Contact Frick if assistance is required.

5. The compressor motor Current Transformer (CT) can be installed on any one phase of the compressor leads.

**NOTICE**

The CT must see all the current on any one phase, therefore in wye-delta applications BOTH leads of any one phase must pass through the CT.
CURRENT TRANSFORMER SIZE

Calculate (CT) size using the following formula where SF is Service Factor and FLA is Full Load Amps of the Motor.

\[ \text{FLA} \times \text{SF} \times 1.1 \] (round up to the next hundred)

Example: FLA = 379; Service Factor = 1.15

\[ 379 \times 1.15 \times 1.1 = 479 \]

Use a 500:5 CT

**DO NOT** use undersized current transformers since the panel will not be capable of reading potential current. If the CT is higher than calculated, enter it’s value for [CT Factor] on the panel. The unit can operate with a CT one size larger than calculated, however, replace with the proper size ASAP.

**NOTICE**

**DO NOT** operate unit with a CT more than one size larger than recommended.

MINIMUM BURDEN RATINGS

The following table gives the minimum CT burden ratings. This is a function of the distance between the motor starting package and the compressor unit.

<table>
<thead>
<tr>
<th>BURDEN RATING</th>
<th>MAXIMUM DISTANCE FROM FRICK PANEL</th>
</tr>
</thead>
<tbody>
<tr>
<td>ANSI</td>
<td>USING # 14 AWG</td>
</tr>
<tr>
<td>B-0.1</td>
<td>2.5</td>
</tr>
<tr>
<td>B-0.2</td>
<td>5</td>
</tr>
<tr>
<td>B-0.5</td>
<td>12.5</td>
</tr>
</tbody>
</table>

**NOTICE**

Do not install a compressor HAND/OFF/AUTO switch in the starter package as this would bypass the compressor safety devices.

CONTROL POWER REGULATOR

Compressor units that will be used in areas that suffer brownouts and other significant power fluctuations can be supplied with a control power regulator. See Figure 15, Recommended Regulator Installation.
Operation

OPERATION and START-UP INSTRUCTIONS

The Frick RXF Rotary Screw Compressor Unit is an integrated system consisting of six major subsystems:

Control Panel – See publications 090.040-O, M, & CS for QUANTUM™ HD; Compressor; Compressor Lubrication System; Compressor Oil Separation System; Compressor Hydraulic System; Compressor Oil Cooling System.

The information in this section of the manual provides the logical step-by-step instructions to properly start up and operate the RXF Rotary Screw Compressor Unit.

NOTICE

For alarm descriptions and shutdown or cutout parameters, see publication 090.040-O.

WARNING

THE FOLLOWING SUBSECTIONS MUST BE READ AND UNDERSTOOD BEFORE ATTEMPTING TO START OR OPERATE THE UNIT.

RXF COMPRESSOR

The Frick RXF rotary screw compressor utilizes mating asymmetrical profile helical rotors to provide a continuous flow of refrigerant vapor and is designed for high pressure applications. The compressor incorporates the following features:

1. High capacity roller bearings to carry radial loads at both the inlet and outlet ends of the compressor.
2. Heavy-duty angular contact ball bearings to carry axial loads are mounted at the discharge end of compressor.
3. Moveable slide valve to provide infinite step capacity control from 100% to 25% of full load capacity.
4. VOLUMIZER II adjusts to the most efficient of three volume loadings at the discharge end of compressor.
5. Provides oil pressure for development of balance load on the oil separator. This valve causes the oil separator to develop oil pressure rapidly on initial start in order to lubricate the compressor rotors out the compressor outlet and back to the oil separator. For normal high-stage operation an oil pump is not required.
6. Compressor housing suitable for 350 PSI pressure.
7. Most bearing and control oil is vented to closed threads in the compressor instead of suction port to avoid performance penalties from superheating suction gas.
8. The shaft seal is designed to maintain operating pressure on the seal well below discharge pressure for increased seal life.
9. Oil is injected into the rotors to maintain good volumetric and adiabatic efficiency, even at very high compression ratios.

WARNING

It is mandatory that the coupling center be removed and the direction of motor rotation be confirmed before running the compressor. Proper rotation of the compressor shaft is clockwise looking at the end of the compressor shaft. Failure to follow this step could result in backward compressor rotation which can cause compressor failure or explosion of the suction housing.

COMPRESSOR LUBRICATION SYSTEM

The RXF compressor is designed specifically for operation without an oil pump for high stage service. Boosters and some low-differential pressure applications will require the demand pump option.

The lubrication system on an RXF screw compressor unit performs several functions:

1. Lubricates the rotor contact area, allowing the male rotor to drive the female rotor on a cushioning film of oil.
2. Provides lubrication of the bearings and shaft seal.
3. Serves to remove the heat of compression from the gas, keeping discharge temperatures low and minimizing refrigerant or oil breakdown.
4. Fills gas leakage paths between or around the rotors with oil, thus greatly reducing gas leakage and maintaining good compressor performance even at high compression ratios.
5. Provides oil pressure for development of balance load on the balance pistons to reduce bearing loading and increase bearing life.

NO PUMP OIL SYSTEM

The RXF screw compressor unit is designed to be self-lubricating. Oil being supplied to the compressor from the oil separator is at system head pressure. Within the compressor, oil porting to all parts of the compressor is vented back to a point in the compressor’s body that is at a pressure lower than compressor discharge pressure. The compressor’s normal operation makes the compressor unit operate essentially as its own oil pump. All oil entering the compressor is moved by the compressor rotors out the compressor outlet and back to the oil separator. For normal high-stage operation an oil pump is not required.

COLD-START SYSTEM

The RXF package is equipped with a special "cold-start" discharge check valve on the gas outlet connection of the oil separator. This valve causes the oil separator to develop oil pressure rapidly on initial start in order to lubricate the compressor without requiring an oil pump, even in cold ambient temperatures with all pressures equalized. See Figure 16.

For high-stage packages, the cold-start valve is equipped with a large spring that creates 30 psi of pressure in the oil separator (above suction pressure), for lubrication of the compressor.

CAUTION

DO NOT ATTEMPT TO SERVICE THE COLD-START VALVE. PLEASE CONTACT THE FRICK SERVICE DEPARTMENT.

Once the compressor is running it will begin to force gas to the condenser at connection P2. See Figure 16. As the condenser heats up it will begin to rise in pressure as the compressor suction pulls down in pressure. As soon as differential pressure is developed between the condenser and suction, these pressures act across a piston inside the cold-start valve to partially overcome the spring force. When the differential pressure reaches and exceeds 30 psi, the piston fully overcomes the spring force and powers the valve fully open for very low operating pressure drop.
For booster applications, the valve is equipped with a lighter spring which produces 1/2 bar (7 psig) oil pressure above suction pressure before it fully powers open. The heavier spring is not required because booster compressors are equipped with a demand oil pump.

The RXF package is also equipped with a suction check valve bypass. The oil separator will slowly bleed down to system suction pressure when the unit is stopped. This allows the compressor drive motor to have an easier start, and the discharge check valve will seat more tightly. See the "SUCTION CHECK VALVE BYPASS" section for operation.

Figure 16 - "Cold-Start" Discharge Check Valve

DEMAND PUMP OIL SYSTEM

This system is designed to provide adequate compressor lubrication for some high stage applications that operate with low differential pressure across the compressor suction and discharge and all booster applications.

On start-up, Quantum™HD will calculate the pressure differential between the compressor discharge and the main oil injection port. If this differential is less than 35 psi, then the demand pump will turn on and will continue to run until 45 psi differential is obtained. Then, the pump will shut down and start only when the differential pressure falls below 35 psi.

NOTICE

For alarm descriptions and shutdown or cutout parameters, see publication 090.040-O.

COMPRESSOR OIL SEPARATION SYSTEM

The RXF is an oil-flooded screw compressor. Most of the oil discharged by the compressor separates from the gas flow in the oil charge reservoir. Some oil, however, is discharged as a mist which does not separate readily from the gas flow and is carried past the oil charge reservoir. The coalescer filter element then coalesces the oil mist into droplets, the droplets of oil fall to the bottom of the coalescer section of the oil separator. The return of this oil to the compressor is controlled by a hand expansion valve (HV1). See Figure 17.

NOTICE

Open HV1 only enough to keep the coalescer end of the separator free of oil.

COMPRESSOR HYDRAULIC SYSTEM

The hydraulic system of the RXF compressor utilizes oil pressure from internally drilled passages in the compressor casing to selectively load and unload the compressor by applying this pressure to the actuating hydraulic piston of the movable slide valve (MSV). It also uses oil pressure to actuate a hydraulic piston that moves the movable slide stop, Volumizer II. This allows adjustment of the compressor volume ratio, (Vi) while the compressor is running.

CAPACITY CONTROL

COMPRESSOR LOADING: The compressor loads when MSV solenoid coil YY2 is energized and oil flows from the solenoid valve through the needle valve (HV2) to compressor port 2, where it enters the load side of the slide valve piston. This equalizes the force on the slide valve piston and discharge pressure on the slide valve area loads the compressor. See Figure 18.

COMPRESSOR UNLOADING: The compressor unloads when MSV solenoid YY1 is energized and oil is allowed to flow from compressor port 2 thru the needle valve to the MSV solenoid. This allows discharge pressure on the slide valve piston to unload the slide valve as the piston moves outward.

ADJUSTMENT (Capacity Control): A needle valve (HV2) is provided to adjust slide valve travel time, preventing excessive slide valve “hunting”. HV2 should be adjusted to restrict oil flow to the compressor port so that slide valve travel time from full load to full unload, or vice versa, is a minimum of 30 seconds.
**NOTICE**

A change in operating conditions, such as winter-to-summer operation, may require readjustment of slide valve travel time.

![Vi control diagram](image)

---

**VOLUMIZER II Vi CONTROL**

The RXF compressor is equipped with a special internal control that automatically adjusts the compressor volume ratio to the most efficient of three available steps, (2.2, 3.5, or 5.0 volume ratio). This gives the compressor the ability to operate at varying operating conditions while minimizing power consumption by avoiding over or undercompression.

Solenoid valves 3 and 4 (See Figures 19 - 21 and location on P & I diagram represented by YY3 and YY4) control the Volumizer II volume ratio control. Oil is internally ported to apply hydraulic pressure to two stepping pistons in order to move the moveable slide stop to the optimum position. The following chart shows the logic of solenoid operation to adjust the volume ratio.

<table>
<thead>
<tr>
<th>Vi</th>
<th>SOLENOID 3 / YY3</th>
<th>SOLENOID 4 / YY4</th>
</tr>
</thead>
<tbody>
<tr>
<td>2.2</td>
<td>Energized</td>
<td>Energized</td>
</tr>
<tr>
<td>3.5</td>
<td>Deenergized</td>
<td>Energized</td>
</tr>
<tr>
<td>5.0</td>
<td>Deenergized</td>
<td>Deenergized</td>
</tr>
</tbody>
</table>

Proper operation of the Volumizer II control can be checked as follows.

1. Set the compressor Vi to 2.2, then record the voltage that is shown on the Slide Valve calibration screen for the current Slide Valve and 0% Slide Valve positions. The difference between these voltages must be in the 1.35 – 1.65 Vdc range.

2. Set the compressor Vi to 3.5, then record the voltage that is shown on the Slide Valve calibration screen for the current Slide Valve and 0% Slide Valve positions. The difference between these voltages must be in the 0.95 – 1.15 Vdc range.

3. Set the compressor Vi to 5.0, then record the voltage that is shown on the Slide Valve calibration screen for the current Slide Valve and 0% Slide Valve positions. The difference between these voltages must be in the 0.73 – 0.93 Vdc range.

4. If the above voltage measurements are all in range, the Volumizer II is working properly. If any of the voltages are out of range, go to the troubleshooting section.

Proper installation of the Vi control valves and gaskets is essential to the operation of this equipment. Incorrectly installed parts may cause the compressor to operate at the wrong Vi, or to load or unload improperly. Operation at the wrong compressor Vi can cause excessive power consumption, noise, vibration, or excessive oil foaming. See Figures 19 - 21 for correct installation of gaskets and location of solenoids.

---

**SLIDE VALVE CALIBRATION**

Slide valve calibration is performed on the Quantum™HD control panel in automatic mode. If further problems occur or persist, contact Johnson Controls-Frick service.
COMPRESSOR OIL COOLING SYSTEMS

The RXF unit can be equipped with one of several systems for controlling the compressor oil temperature. They are single or dual-port liquid injection, thermosyphon, or water-cooled oil coolers. Each system is automatically controlled, independent of compressor loading or unloading.

Oil cooling systems maintain oil temperature within the following ranges for R-717:
- Liquid Injection Oil Cooling: 130 to 150°F
- External* Oil Cooling: 120 to 140°F
- * Thermosyphon Oil Cooling (TSOC) or Water-Cooled Oil Cooling (WCOC).

SINGLE-PORT LIQUID INJECTION

The single-port liquid injection system is designed to permit liquid refrigerant injection into one port on the compressor at any given moment and operates as outlined.

The liquid injection solenoid valve is energized by the microprocessor when the temperature sensor, installed in the compressor discharge, exceeds the setpoint. High-pressure liquid refrigerant is then supplied to the motorized expansion valve. Refer to P & I DIAGRAMS section for piping and instrumentation drawings.

DUAL-PORT LIQUID INJECTION

The dual-port liquid injection system is designed to obtain the most efficient compressor performance at high and low compression ratios by permitting injection of liquid refrigerant into one of two ports optimally located on the compressor. This minimizes the performance penalty incurred with liquid injection oil cooling.

The dual-port system contains all the components of the single-port system with the addition of a 3-way motorized valve and operates as outlined.

The liquid injection solenoid valve is energized by the microprocessor when the temperature sensor, installed in the compressor discharge, exceeds the setpoint. Liquid refrigerant is then passed through the motorized expansion valve to the 3-way motorized valve. Depending on the compressor’s operating volume ratio (Vi), the microprocessor will select the flow of the liquid refrigerant to the optimum compressor port.

---

**QUANTUM™HD EZ-COOL™ LIQUID INJECTION ADJUSTMENT PROCEDURE**

**DESCRIPTION:** This screen allows the user to enter and view the basic operating parameters related to EZ Cool LIOC PI control.

The following are the EZ Cool LIOC Setup screen selections available on this screen:

**EZ COOL PI CONTROL**

- **[Setpoint]** - Enter the value that you wish to control to.
- **[Proportional Band]** – This setpoint determines the size of a region either above or below the Control Setpoint. Within this region, the Proportional component of the PI Output value is the number between 0% and 100% that directly...
corresponds to the difference between the Control Input (Actual) and the Control Setpoint (Setpoint). Outside of this region, the Proportional component is either 100% or 0%. If the PI’s Action is Forward, the Proportional Band extends above the Control Setpoint. If the PID’s Action is Reverse, the Proportional Band extends below the Control Setpoint.

[Integration Time] - This setpoint controls the influence that the Integral component exerts on the PI Output value. The Integral component works to push the Control Input toward the Control Setpoint by tracking the difference between the Control Input and the Control Setpoint over time.

High Limit - The highest value that the output can be.

Low Limit - The lowest value that the output can be.

I/O Board - One of the following will be shown:
- None
- Analog Board 1
- Analog Board 2

I/O Channel - The output channel that will be used will be shown.

Port Multiplier - The standard value is 1 (one).

DIGITAL CONTROL

An output is provided for an optional Liquid Injection solenoid valve. The function of this output is only available if the compressor has Liquid Injection oil cooling and it has been enabled. Liquid Injection controls the supply of liquid refrigerant to the compressor. Liquid Injection is off (the solenoid is closed) if the compressor is off.

[On When Above] - When the Discharge Temperature is above this setpoint, the Liquid Injection solenoid output will energize, until the Discharge Temperature drops below this setpoint.

[Off When Below] - When the Discharge Temperature is below this setpoint, the Liquid Injection solenoid output will de-energize, until the Discharge Temperature raises above this setpoint.

STATUS

Discharge Temperature - The actual Discharge temperature is shown here.

Control Output - The value of the Output signal as controlled by the PI. This is not a setpoint value.

Valve Position - The value shown here represents the position of the valve with relationship to the Control Output.

OPERATION OF DANFOSS LIQUID INJECTION VALVE

The Danfoss ICAD (Industrial Control Actuator with Display) is equipped with an LED Interface from which it is possible to monitor and change the setting of parameters to adapt the ICAD and the corresponding ICM (Motorized Industrial Control Valve) to the actual refrigeration application.

The setting of parameters is managed by means of the integrated ICAD (Figures 23 and 24) and consists of:

- "Down" arrow push button (Figures 23 and 24)
  - Decreases parameter number by 1 at each activation.
- "Up" arrow push button (Figures 23 and 24)
  - Increases parameter number by 1 at each activation.

- Enter push button (Figures 23 and 24)
  - Gives access to the Parameter list by keeping the push button activated for 2 seconds. A Parameter list example is shown below (parameter \text{i\text{08}}, Figure 25).

- Gives access to change a value once the Parameter list has been accessed.
- Acknowledge and save change of value of a parameter.
- To exit from the Parameter list and return to the display of Opening Degree (OD), keep the push button activated for 2 seconds.

- Display (Figure 26)
  - Normally the Opening Degree (OD) 0 - 100% of the ICM valve is displayed. No activation of push buttons for 20 seconds means that the display will always show 0 (Figure 25).

- Figures
  - Displays the parameter.
  - Displays the actual value of a parameter.
  - Displays the function status by means of text (Figure 23).
    - **Mod** represents that ICAD is positioning the ICM valve according to an analog input signal (Current).
    - **Low** represents that ICAD is operating the ICM valve like an ON/OFF solenoid valve with low speed according to a digital input signal.
    - **Med** represents that ICAD is operating the ICM valve like an ON/OFF solenoid valve with medium speed according to a digital input signal.
    - **High** represents that ICAD is operating the ICM valve like an ON/OFF solenoid valve with high speed according to a digital input signal (Figure 27).

- Alarms - ICAD can handle and display different alarms.

<table>

<td>A2</td>
<td>Internal fault inside electronics</td>
</tr>
<tr>
<td>All input error</td>
<td>A3</td>
<td>When input amps are &gt; 22 mA</td>
</tr>
</tbody>
</table>

Reset to factory setting:
1. Remove the power supply.
2. Activate down arrow and up arrow push buttons at the same time.
3. While continuing to push the down and up arrows, connect the power supply.
4. Release down arrow and up arrow push buttons.
5. When the display on ICAD (Figure 23) is alternating between showing: CA and A1 the factory resetting is complete.

Typically motorized valves are factory set. If adjustments are needed, the following procedure can be used.

1. Ensure that there is power to the valve (24 VDC) and all wiring is complete prior to configuring the motorized valve. The ICAD 600 requires 1.2 amps for operation and the ICAD 900 requires 2.0 amps.
2. Identify which actuator is being used (ICAD 600 or 900) and which motorized valve is being used (ICM 20, 25, 32, 40, 50, or 65). Ensure that the correct actuator is being used with the ICM valve as follows:
   - ICM20 with ICAD 600
   - ICM25 with ICAD 600
   - ICM32 with ICAD 600
   - ICM40 with ICAD 900
   - ICM50 with ICAD 900
   - ICM65 with ICAD 900
3. When the valve is initially powered, A1 and CA will be flashing on the LED display. Hold the enter button down for two seconds until these values stop flashing.
4. Push the down arrow button and scroll until j10 is displayed and push the enter button. Using the up arrow, scroll until j11 is displayed and push the enter button. This step must be completed within 20 seconds or the valve will reset.
5. Push the down arrow button again and scroll until j26 is displayed and push the enter button. Identify the ICM valve being used and push the up arrow until the correct number is displayed for the ICM valve and then push the enter button. The values are as follows:
   - 1 for ICM20
   - 2 for ICM25
   - 3 for ICM32
   - 4 for ICM40
   - 5 for ICM50
   - 6 for ICM65
6. The ICAD will store these parameters with the power removed.

</table>
THERMOSYPHON OIL COOLING

Thermosyphon oil cooling is an economical, effective method for cooling oil on screw compressor units. Thermosyphon cooling utilizes liquid refrigerant at condenser pressure and temperature which is partially vaporized at the condenser temperature in a shell and tube or plate-type vessel, cooling the oil. The vapor, at condensing pressure, is vented to the condenser inlet and reliquified. This method is the most cost effective of all currently applied cooling systems since no compressor capacity loss or compressor power penalties are incurred. The vapor from the cooler need only be condensed, not compressed. Refrigerant flow to the cooler is automatic, driven by the thermosyphon principle, and cooling flow increases as the oil inlet temperature rises.

Figure 28

SYSTEM OPERATION: Liquid refrigerant fills the cooler. Warm or hot oil (above the liquid return temperature) flowing through the cooler will cause some of the refrigerant to boil and vaporize. The vapor rises in the return line. The density of the refrigerant liquid/vapor mixture in the return line is considerably less than the density of the liquid in the supply line. This imbalance provides a differential pressure which sustains a flow condition to the oil cooler. This relationship involves:

1. Liquid height above the cooler.
2. Oil heat of rejection.
3. Cooler size and piping pressure drops.

Current thermosyphon systems are using single-pass oil coolers and flow rates based on 3:1 overfeed.

The liquid/vapor returned from the cooler is separated in the receiver. The vapor is vented to the condenser inlet and reliquified. This method is the most cost effective of all currently applied cooling systems since no compressor capacity loss or compressor power penalties are incurred. The vapor from the cooler need only be condensed, not compressed. Refrigerant flow to the cooler is automatic, driven by the thermosyphon principle, and cooling flow increases as the oil inlet temperature rises.

INITIAL START-UP PROCEDURE

Having performed the checkpoints on the prestart check list (see FORMS section), the compressor unit is ready for start-up. It is important that an adequate refrigerant load be available to load test the unit at normal operating conditions. The following points should be kept in mind during initial start-up.

1. Models 58 - 101 ONLY! It is imperative that during the initial start-up of the package that the hand expansion valve on the main oil injection line is fully open to ensure adequate oil flow. There is still an orifice installed in the compressor to control maximum oil flow. At initial start-up of the package the hand expansion valve must be fully open. After initial start-up of the package the hand expansion valve should be adjusted. There are two methods of determining the correct adjustment of this valve.

The best method to determine target discharge temperature is to run CoolWare™ with the operating conditions of the compressor. The program will give you a theoretical discharge temperature of the compressor. Once this temperature is known, you may adjust the hand expansion valve. The ideal discharge temperature is within 5°F + or – of the theoretical discharge temperature. Adjust the valve to achieve the theoretical discharge temperature. If you do not have access to CoolWare™, 180°F is a good target discharge temperature for a high stage ammonia compressor. Booster applications and compressors using HFC and HCFC refrigerants may run cooler. Compressors with high discharge pressure may run hotter.

The first method is used for compressors with External Oil Cooling (Thermosyphon, Water Cooled, and Glycol Cooled). Before the initial startup of the compressor close the hand expansion valve completely. Open the valve back up and count the turns that it takes to fully open the valve. After the initial startup close the valve to achieve approximately 180°F discharge temperature or the theoretical temperature from CoolWare. Do not fully close the valve at any time while the compressor is running.

The second method is used for compressors with Liquid Injection Oil Cooling. Because the discharge temperature is controlled by the Liquid Injection Thermal Expansion Valve you will not be able adjust for the correct oil flow by using the discharge temperature. Before the initial startup of the compressor close the hand expansion valve completely. Open the valve back up and count the turns that it takes to fully open the valve. After the initial startup close the valve ½ way. If it took 10 turns to open the valve completely, then turn it in 5 turns. If it took 7 turns to open, then close the valve 3½ turns. Do not close the valve any further than ½ the number of turns required to fully open it.

WARNING

Failure to properly adjust this valve can lead to excessive noise and vibration of the compressor and package, premature failure of the bearings, liquid loading of the rotors, liquid starvation of the rotors and catastrophic failure of the compressor.

1. All Models! For proper and safe operation, the compressor must be run at the proper speed and discharge pressure. Exceeding design conditions creates a potential hazard.
2. Rotate and lubricate motor bearings according to manufacturer’s recommendations PRIOR to initial start-up as required.
3. After running the unit for approximately three hours, adjust liquid injection oil cooling if applicable. If unit has water cooled oil cooling, adjust water control valve to cooler.
4. The compressor slide valve linear transmitter should be calibrated.
5. Perform vibration analysis if equipment is available.
6. Pull and clean suction strainer after 24 hours operation. If it is excessively dirty, repeat every 24 hours until system is clean. Otherwise, follow the Maintenance Schedule. See the RECOMMENDED MAINTENANCE PROGRAM section.
NORMAL START-UP PROCEDURE

1. Confirm system conditions permit starting the compressor.
2. Press the [RUN] key.
3. Allow the compressor to start up and stabilize. At start-up, the slide stop (volumizer) and the slide valve (capacity control) are in the AUTO mode.
4. Observe the compressor unit for mechanical tightness of the external piping, bolts and valves. Ensure that the machine is clean from oil and refrigerant leaks. If any of these occur, shut down the compressor and correct the problem as necessary using good safety precautions.
5. RETIGHTEN OIL SEPARATOR COVER BOLTS at condenser design pressure (while system is running) to 90 ft-lb for models 12 – 50.

RE-TIGHTEN MANWAY BOLTS at condenser design pressure (while system is running) to 150 ft-lb for models 58 - 101 (11" x 15" manway); 180 ft-lb on 12" x 16" manway for oversized separator on 85/101 models.

RESTARTING COMPRESSOR UNIT AFTER CONTROL POWER INTERRUPTION (PLANT POWER FAILURE)

1. Check ADJUSTABLE setpoints.
2. Follow normal start-up procedure.

VFD SKIP FREQUENCIES

Criteria for Identifying Elevated Energy on VFD Packages and Establishing “Skip” Frequencies

With the RXF running loaded at full speed, the entire package must be physically checked for elevated energy, including any corresponding extremities such as valves, liquid injection piping, brackets, tubing, oil cooler and oil piping. The VFD speed is to be decreased by 100 rpm increments and the entire package physically checked for elevated energy at each stage until the minimum speed range is reached. As the high energy hot spots are identified, they are to be checked with a vibration meter and any readings that meet or exceed one inch per second must have that frequency range skipped in the microprocessor for the VFD, eliminating the ability of the package to operate within that frequency range. Each identified range needs to have the skip set to as narrow a frequency band as possible, only making it wider until full range is accommodated. Please also reference 070.902-1B for acceptable package vibration readings.

Skip frequencies should be reviewed and verified annually.
Maintenance

This section provides instructions for normal maintenance, a recommended maintenance program, troubleshooting and correction guides, typical wiring diagrams and typical P and I diagrams.

⚠️ WARNING

This section must be read and understood before attempting to perform any maintenance or service to the unit.

NORMAL MAINTENANCE OPERATIONS

When performing maintenance you must take several precautions to ensure your safety:

⚠️ CAUTION

1. IF UNIT IS RUNNING, PUSH [STOP] KEY TO SHUT DOWN THE UNIT.
2. DISCONNECT POWER FROM UNIT BEFORE PERFORMING ANY MAINTENANCE.
3. WEAR PROPER SAFETY EQUIPMENT WHEN COMPRESSOR UNIT IS OPENED TO ATMOSPHERE.
4. ENSURE ADEQUATE VENTILATION.
5. TAKE NECESSARY SAFETY PRECAUTIONS REQUIRED FOR THE REFRIGERANT BEING USED.

⚠️ WARNING

CLOSE ALL COMPRESSOR PACKAGE ISOLATION VALVES PRIOR TO SERVICING THE UNIT. FAILURE TO DO SO MAY RESULT IN SERIOUS INJURY.

GENERAL MAINTENANCE

Proper maintenance is important in order to assure long and trouble-free service from your screw compressor unit. Some areas critical to good compressor operation are:

1. Keep refrigerant and oil clean and dry, avoid moisture contamination. After servicing any portion of the refrigeration system, evacuate to remove moisture before returning to service. Water vapor condensing in the compressor while running, or more likely while shut down, can cause rusting of critical components and reduce life.

2. Keep suction strainer clean. Check periodically, particularly on new systems where welding slag or pipe scale could find its way to the compressor suction. Excessive dirt in the suction strainer could cause it to collapse, dumping particles into the compressor.

3. Keep oil filters clean. If filters show increasing pressure drop, indicating dirt or water, stop the compressor and change filters. Running a compressor for long periods with high filter pressure drop can starve the compressor for oil and lead to premature bearing failure.

4. Avoid slugging compressor with liquid refrigerant. While screw compressors are probable the most tolerant to ingestion of some refrigerant liquid of any compressor type available today, they are not liquid pumps. Make certain to maintain adequate superheat and properly size suction accumulators to avoid dumping liquid refrigerant into compressor suction.

Keep liquid injection valves properly adjusted and in good condition to avoid flooding compressor with liquid. Liquid can cause a reduction in compressor life and in extreme cases can cause complete failure.

5. Protect the compressor during long periods of shut down. If the compressor will be setting for long periods without running it is advisable to evacuate to low pressure and charge with dry nitrogen or oil, particularly on systems known to contain water vapor.

6. Preventive maintenance inspection is recommended any time a compressor exhibits a noticeable change in vibration level, noise or performance.

COMPRESSOR SHUTDOWN and START-UP

For seasonal or prolonged (six months) shutdown, use the following procedure:

1. Push [STOP] key to shut down unit.
2. Open disconnect switch for compressor motor starter.
3. Turn off power.
4. Isolate the package by closing all package valves to the system. Tag all closed valves.

⚠️ CAUTION

Open any solenoid valves or other valves that may trap liquid between the isolation valves and other package valves to prevent injury or damage to components.

5. With liquid injection, close the manual hand valve upstream of the solenoid and manually open the solenoid by turning "in" the manual opening stem (clockwise viewed from below valve).

6. Shut off the cooling water supply valve to the oil cooler. Drain water, if applicable. Attach CLOSED tags.

7. Protect oil cooler from ambient temperatures below freezing.

NOTICE

The unit should be inspected monthly during shutdown. Check for leaks or abnormal pressure. Use the maintenance log to record readings to verify the pressure stability of the unit. To prevent the seals and bearing from drying out, run oil pump (if available) and manually rotate the compressor shaft. Consult motor manufacturer for motor recommendations.

TO START UP AFTER SEASONAL OR PROLONGED SHUTDOWN, USE THE FOLLOWING PROCEDURE:

2. Any water necessary for the operation of the system that may have been drained or shut off should be restored or turned on.
3. Reset solenoid valves to automatic position, then open all valves previously closed. Remove tags.
4. Compressor unit is ready for prestart checks. Refer to PRESTART CHECKLIST.
COMPRESSOR/MOTOR SERVICING

Before removing the motor from an RXF unit, it is critical that proper support be provided for the compressor to prevent damage to the oil separator. Insert blocks or a jack between the separator shell and compressor casting. Make sure the weight is held safely by the separator shell. Loosen the compressor discharge flange bolts to relax any flange and pipe stress, then carefully remove the motor. Similarly, before removing the compressor for servicing, the back end of the motor must be supported to prevent damage. Again, insert either blocks or a jack between the rear of the motor and the separator shell.

GENERAL INSTRUCTIONS FOR REPLACING COMPRESSOR UNIT COMPONENTS

When replacing or repairing components which are exposed to refrigerant, proceed as follows:

1. Push [STOP] key to shut down the unit.
2. Open disconnect switches for compressor motor starter and oil pump motor starter (if applicable).
3. Isolate the package by closing all package valves to the system. Tag all closed valves.

- **CAUTION**
  - Open any solenoid valves or other valves that may trap liquid between the isolation valves and other package valves to prevent injury or damage to components.

4. SLOWLY vent separator to low-side system pressure using the suction check valve bypass.

- **NOTICE**
  - Recover or transfer all refrigerant vapor, in accordance with local ordinances, before opening to atmosphere. The separator MUST be equalized to atmospheric pressure.

5. Make replacement or repair.
6. Isolate the low pressure transducer, PE-4, to prevent damage during pressurization and leak test.
7. Pressurize unit and leak test.
8. Evacuate unit to 29.88" Hg (1000 microns).
9. Open all valves previously closed and reset solenoid valves to automatic position. Remove tags.
10. Close disconnect switches for compressor motor starter and oil pump motor starter, if applicable.
11. Unit is ready to put into operation.

OIL FILTER, SPIN-ON (RXF 12 – 50)

To change the filter proceed as follows:

1. Push [STOP] key to shut down the unit. Open disconnect switches for the compressor.
2. Isolate the package by closing all package valves to the system. Tag all closed valves.

- **CAUTION**
  - Open any solenoid valves or other valves that may trap liquid between the isolation valves and other package valves to prevent injury or damage to components.

SLOWLY vent separator to low-side system pressure using the suction check valve bypass.

- **NOTICE**
  - Use of oil filters other than Frick may cause warranty claim to be denied.

4. Replace with new oil filter element. Make finger tight plus an additional half turn.
5. Isolate the low pressure transducer, PE-4, to prevent damage during pressurization and leak test.
6. Pressurize and leak test.
7. Evacuate unit to 29.88" Hg (1000 microns).
8. Open the suction and discharge service valves, and the low pressure transducer. Close disconnect switches for the compressor. Start the unit.

OIL FILTER (OF-1) CARTRIDGE STYLE (58 – 101)

RXF compressor units are furnished with one main oil filter (OF-1). A second oil filter (OF-2) is installed as optional equipment to facilitate the changing of the filter element(s) without unit shutdown.

- **NOTICE**
  - Use of oil filters other than Frick may cause warranty claim to be denied.

To change the filter cartridge proceed as follows:

1. If a single oil filter is installed, push [STOP] key to shut down the unit. Open disconnect switches for the compressor and (if applicable) oil pump motor starters.

If dual oil filters are installed, open the outlet, then inlet service valves of the standby filter.

- **WARNING**
  - Open inlet service valve slowly to prevent a sudden pressure drop which could cause an oil filter differential alarm.
2. Close outlet then inlet service valves of filter being serviced.

3. Open bleed valve and purge pressure from the oil filter cartridge.

4. Close discharge service valve. SLOWLY vent the separator to low-side system pressure using the suction check valve bypass. Close suction valve and suction check valve bypass.

5. Close oil filter isolation valves. Open drain valve on oil filter head and drain the oil. Remove the canister cover. Discard the cartridge and gasket.

6. Flush the filter body with clean Frick refrigeration oil; wipe dry with a clean, lint-free cloth; and close drain valve.

7. Place a new cartridge in the filter canister. Replace the gasket and spring and reinstall the canister cover. Torque cover bolts in sequence to:
   a. Finger tight
   b. 17 ft-lb
   c. 35 ft-lb

8. Isolate the low pressure transducer, PE-4, to prevent damage during pressurization and leak test.

10. Evacuate the unit to 29.88" Hg (1000 microns).

11. Add 2 gallons of oil by attaching a suitable pressure-type hose to the oil-charging valve located on top of the separator. Use a pressure-type oil pump and recommended Frick oil.

12. Open the suction and discharge service valves, oil filter isolation valves, and the low pressure transducer. Readjust suction check valve bypass. Close disconnect switches for the compressor and (if applicable) the oil pump motor starters. Start the unit.

COALESCELER OIL RETURN STRAINER

1. Push [STOP] key to shut down the unit, then open disconnect switches for the compressor.

2. Isolate the package by closing all package valves to the system. Tag all closed valves.

3. Close strainer isolation valves. Remove the large plug from the bottom of the strainer and remove the element from the strainer.

4. Wash the element in solvent and blow clean with air.

5. Replace the cleaned element and removed plug. Open strainer isolation valves.

6. Isolate the low pressure transducer, PE-4, to prevent damage during pressurization and leak test.

7. Pressurize and leak test. Evacuate unit to 29.88" Hg (1000 microns).

8. Open the suction and discharge service valves, and the low pressure transducer. Close disconnect switches for the compressor. Start the unit.

LIQUID INJECTION STRAINER

To clean the liquid injection strainer the unit must be shut down. The procedure is as follows:

1. Push [STOP] key to shut down the unit, then open disconnect switches for the compressor.

2. Close the liquid supply service valve located before the liquid solenoid.

3. Immediately screw in the manual solenoid valve stem to relieve liquid refrigerant pressure trapped between the solenoid and the service valve.

4. Close the service valve located between the compressor and the liquid injection thermal expansion valve.

5. Carefully loosen capscrews securing the strainer cover to the strainer. Allow pressure to relieve slowly.

6. When all entrapped refrigerant has been relieved, carefully remove loosened capscrews (as liquid refrigerant is sometimes caught in the strainer), strainer cover, and strainer basket.

7. Wash the strainer basket and cover in solvent and blow clean with air.

8. Reassemble the strainer.

9. Open the service valve between the compressor and the liquid injection thermal expansion valve, purge entrained air, and check for leakage.

10. Screw out the manual solenoid valve stem.

11. Carefully open the liquid supply service valve.

12. Leak test.

13. Close disconnect switches for compressor starter.

14. Start the unit.

OIL PUMP STRAINER (Optional)

To clean the full-lube oil pump strainer, the unit must be shut down. The procedure is as follows:

1. Push [STOP] key to shut down the unit, then open the disconnect switches for the compressor and (if applicable) the oil pump motor starters.

2. Recover or transfer all refrigerant vapor, in accordance with local ordinances, before opening to atmosphere. The separator MUST be equalized to atmospheric pressure.

3. Open any solenoid valves or other valves that may trap liquid between the isolation valves and other package valves to prevent injury or damage to components. SLOWLY vent separator to low-side system pressure using the suction check valve bypass.

4. CAUTION

Oil entrained refrigerant may vaporize, causing a separator pressure increase. Repeat transfer and recovery procedure, if necessary.
2. Close strainer service valves.
3. Open the drain valve located in the strainer cover and drain the oil into a container.
4. Remove the capscrews securing the strainer cover, strainer cover gasket, and element. Retain the gasket.
5. Wash the element in solvent and blow it clean with air.
6. Wipe the strainer body cavity clean with a lint-free clean cloth.
7. Replace the cleaned element and gasket, then reattach the cover using the retained capscrews.
8. Reinstall the drain plug and open the strainer service valves.
9. Check for leakage.
10. Close the disconnect switches for the compressor and (if applicable) the oil pump motor starters.
11. Start the unit.

**SUCTION CHECK VALVE BYPASS**

A 1/4" angle valve is installed between the compressor and suction flange that can be used as a suction valve bypass. This feature has several uses including reducing starting torque, improving oil quality, and relieving the refrigerant to low side for servicing.

In most cases, the valve should be left open approximately 1 to 2 turns at all times. If the compressor back-spins or too much oil foaming is experienced while venting, partially close valve to slow speed of equalization. If system is on AUTO CYCLE and short cycling occurs, the valve must be closed.

To relieve refrigerant to low side, close separator discharge service valve. Slowly open bypass valve (if closed) and wait for pressure to equalize. Close bypass and suction service valves before evacuating the unit.

**COALESCER FILTER ELEMENT**

**CAUTION**

Use of coalescer filter elements other than Frick may cause warranty claim to be denied.

When changing the coalescer filter element, it is recommended that the oil and oil filter be changed. Applicable strainer elements should be removed and cleaned.

1. Refer to CHANGING OIL, Steps 1 thru 8.
2. Remove coalescer head and gasket. Discard the gasket.
3. Remove and retain nut securing coalescer filter retainer.
4. Remove retainer, coalescer filter element(s), and two O-rings. Discard the filter element(s).
5. Install new coalescer filter element(s).

**NOTICE**

Frick SuperCoalescer™ element (with drain feature), on Models 24–101, must be installed with the "DRAIN DOWN" tag on the bottom at the 6 o’clock position.

**CAUTION**

Oil entrained refrigerant may vaporize, causing a separator pressure increase. Repeat transfer and recovery procedure, if necessary.

1. Push [STOP] key to shut down the unit.
2. Open disconnect switch for the compressor motor starter.
3. Close liquid injection service valves (if applicable).
4. Close discharge service valve. SLOWLY vent the separator to low-side system pressure using the suction check valve bypass. Close suction valve.

**NOTICE**

Recover or transfer all refrigerant vapor, in accordance with local ordinances, before opening to atmosphere. The separator MUST be equalized to atmospheric pressure.

5. Open drain valve(s) located on the underside of the separator and drain the oil.
6. Drain oil filter, strainers, and oil cooler, if applicable.
7. Remove and install new oil filter element.
8. Remove, clean, and reinstall strainer elements in strainers.
9. Evacuate unit to 29.88” Hg (1000 microns).
10. Open suction service valve and pressurize the unit to system suction pressure. Close the suction valve and leak test.
11. Add oil by attaching a suitable pressure-type hose to the oil drain valve located on top of the separator. Using a pressure-type oil pump and recommended Frick oil, open the drain valve and fill the separator until oil level is midway in the top sight glass.
Evacuation of the oil separator will assist the flow of oil into the unit. Also, fill slowly because oil will fill up in the separator faster than it shows in the sight glass. See Oil Charge section.

12. Open discharge and liquid injection service valves.
14. Start the unit.

SUCTION STRAINER CLEANING PROCEDURE

1. Open disconnect switch.
2. Isolate the package by closing all package valves to the system. Tag all closed valves.

CAUTION
Open any solenoid valves or other valves that may trap liquid between the isolation valves and other package valves to prevent injury or damage to components.

3. With liquid injection, close the manual hand valve upstream of YY7 and manually open YY7 by turning in the manual opening stem (clockwise viewed from below valve).

CAUTION
Failure to follow this procedure will damage valve YY7.

4. SLOWLY vent the separator to low-side system pressure using the suction check valve bypass.

NOTICE
Recover or transfer all refrigerant vapor, in accordance with local ordinances, before opening to atmosphere. The separator MUST be equalized to atmospheric pressure.

CAUTION
Oil entrained refrigerant may vaporize, causing a separator pressure increase. Repeat transfer and recovery procedure, if necessary.

5. Remove cover plate.
6. Remove strainer.
7. Clean strainer.
8. Reinstall the strainer in the proper direction (outboard end is marked) and replace the gasket.

CAUTION
If the strainer is installed backwards, it will be damaged.

10. First, reset solenoid valves to automatic position then open all valves previously closed. Remove tags. Close disconnect switches for compressor. Start unit.

DEMAND PUMP DISASSEMBLY

DANGER
BEFORE OPENING ANY VIKING PUMP LIQUID CHAMBER (PUMPING CHAMBER, RESERVOIR, JACKET, ETC.) ENSURE:
1. THAT ANY PRESSURE IN THE CHAMBER HAS BEEN COMPLETELY VENTED THROUGH SUCTION OR DISCHARGE LINES OR OTHER APPROPRIATE OPENINGS OR CONNECTIONS.
2. THAT THE DRIVING MEANS (MOTOR, TURBINE, ENGINE, ETC.) HAS BEEN “LOCKED OUT” OR MADE NONOPERATIONAL SO THAT IT CANNOT BE STARTED WHILE WORK IS BEING DONE ON THE PUMP.

FAILURE TO FOLLOW ABOVE LISTED PRECAUTIONARY MEASURES MAY RESULT IN SERIOUS INJURY OR DEATH.

1. Mark head and casing before disassembly to ensure proper reassembly. The idler pin, which is offset in the pump head, must be positioned up and equal distance between port connections to allow for proper flow of liquid through the pump.

2. Remove the head capscrews.

3. Tilt top of head back when removing to prevent idler from falling off idler pin.

4. Remove idler and bushing assembly. If idler bushing needs replacing, see INSTALLATION OF CARBON GRAPHITE BUSHINGS.

5. Insert a brass bar or piece of hardwood in the port opening and between the rotor teeth to keep the shaft from turning. Turn the locknut counterclockwise and remove locknut. See Figure 29 or 30.

6. Loosen the two setscrews in the face of bearing housing and turn the thrust bearing assembly counterclockwise and remove from casing. See Figure 29 or 30.

7. GG, HJ, HL: Remove the snap ring from the shaft. See Figure 29. AS, AK, AL: Remove the bearing spacer from the shaft. See Figure 30.

8. Remove the brass bar or piece of hardwood from the port opening.

9. The rotor and shaft can now be removed by tapping on the end of the shaft with a lead hammer or, if using a regular

Figure 29 - Thrust-Bearing assembly (GG, HJ, HL)
hammer, use a piece of hardwood between the shaft and hammer. The rotary member of the seal will come out with the rotor and shaft.

10. **AS, AK, AL**: Remove the bearing retainer washer. The washer may have stayed with rotor and shaft when removed or is against ball bearing. See Figure 30.

11. Remove the mechanical seal rotary member and spring from the rotor and shaft assembly.

12. **GG, HJ, HL**: Remove inner snap ring and single-row ball bearing from the casing.

**AS, AK, AL**: Remove single-row ball bearing from casing.

13. Remove seal seat or stationary part of seal from casing.

**GG, HJ, HL**: Remove outer snap ring from the bearing housing and remove the ball bearing. See Figure 29.

**AS, AK, AL**: Loosen the two set screws in flange outside diameter. Rotate end cap and lip seal counterclockwise and remove. Remove the ball bearing. See Figure 30.

The casing should be examined for wear, particularly in the area between ports. All parts should be checked for wear before the pump is put together.

When making major repairs, such as replacing a rotor and shaft, it is advisable to also install a new mechanical seal. See INSTALLATION OF CARBON GRAPHITE BUSHINGS.

Clean all parts thoroughly and examine for wear or damage. Check lip seals, ball bearings, bushing, and idler pin and replace if necessary. Check all other parts for nicks, burrs, excessive wear and replace if necessary.

Wash bearings in clean solvent. Blow out bearings with compressed air. **Do not allow bearings to spin;** turn them slowly by hand. Spinning bearings will damage the race and balls. Make sure bearings are clean, then lubricate with refrigeration oil and check for roughness. Roughness can be determined by turning outer race by hand. Replace the bearings if they have roughness.

Be sure shaft is free from nicks, burrs and foreign particles that might damage mechanical seal. Scratches on shaft in seal area will provide leakage paths under mechanical seal. Use fine emery cloth to remove scratches or sharp edges.

**DEMAND PUMP ASSEMBLY**

Assembly Notes On Standard Mechanical Seal (Synthetic Rubber Bellows Type)

**NOTICE**

Read carefully before reassembling pump.

The seal used in this pump is simple to install and good performance will result if care is taken during installation. The principle of a mechanical seal is contact between the rotary and stationary members. These parts are lapped to a high finish and their sealing effectiveness depends on complete contact.

Prior to installing the rotary portion of the mechanical seal, prepare and organize the rotor shaft, head and idler assemblies, and appropriate gaskets for quick assembly.

Once the rotary portion of the mechanical seal is installed on the rotor shaft, it is necessary to assemble parts as quickly as possible to ensure that the seal does not stick to the shaft in the wrong axial position. The seal will stick to the shaft after several minutes setting time.

Never touch sealing faces with anything except clean hands or clean cloth. Minute particles can scratch the seal faces and cause leakage.

1. Coat the idler pin with refrigeration oil and place idler and bushing on idler pin in the head. If replacing a carbon-graphite bushing, refer to INSTALLATION OF CARBON GRAPHITE BUSHINGS.

2. Clean rotor hub and casing seal housing bore. Make sure both are free from dirt and grit. Coat outer diameter of seal seat and inner diameter of seal housing bore with refrigeration oil.

3. Start seal seat in seal housing bore. If force is necessary, protect seal face with a clean cardboard disc and gently tap it in place with a piece of wood. Be sure seal seat is completely seated in the bore.
4. Place tapered installation sleeve on shaft. Refer to Figure 32. Sleeve is furnished with GG, AS, AK, and AL replacement mechanical seals. Coat rotor shaft, tapered installation sleeve, and inner diameter of mechanical seal rotary member with a generous amount of refrigeration oil. Petroleum may be used but grease is not recommended.

5. Place seal spring on the shaft against the rotor hub. Refer to Figure 32.

6. Slide rotary member, with lapped contact surface facing away from the spring, over installation sleeve on shaft until just contacting the spring. Do not compress the spring. Remove the installation sleeve.

7. Coat the rotor shaft with refrigeration oil. Install the rotor and shaft into the casing, slowly pushing until the ends of the rotor teeth are just below the face of the casing. Take care not to damage the seal seat.

8. Leave the rotor in this position. Withdrawal of rotor and shaft may displace the carbon seal rotating face and result in damage to the seal.

9. Place O-ring gasket on the head and install head and idler assembly on pump. Pump head and casing were marked before disassembly to ensure proper reassembly. If not, be sure the idler pin, which is offset in pump head, is positioned up and equal distance between port connections to allow for proper flow of liquid through the pump.

10. Tighten the head capscrews evenly.

11. If the pump was equipped with a relief valve and was removed during disassembly, install on the head with new O-Rings or gaskets. The relief valve adjusting screw cap must always point towards the suction port.

12. In 2005, the use of single seal bearings were phased out. Pumps now use “Sealed for Life” bearings that have seals on both sides. The new bearings can be installed either side first and do not need to be packed with grease. For older models with single seal bearings, pack the inner ball bearing with multi-purpose grease, NLGI #2.

AS, AK, AL: Install the bearing retainer washer over the shaft before installing the ball bearing. Install the ball bearing in the casing with sealed side towards head end of the pump. Drive the bearing into the bore. Tap the inner race with a brass bar and lead hammer to position the bearing.

13. GG, HJ, HL: Install the shaft snap ring in groove in the shaft. See Figure 29.

AS, AK, AL: Install the bearing spacer over the shaft and against the single row ball bearing. See Figure 30.

14. Pack the lubrication chamber between the inner ball bearing and double row ball bearing in the thrust bearing assembly approximately one-half full of multi-purpose grease, NLGI #2. The thrust bearing assembly will take the remaining space. See Figures 29 or 30.

15. Pack the double row ball bearing with multipurpose grease, NLGI #2.

GG, HJ, HL: Install the ball bearing into the bearing housing with shield side toward the coupling end of the shaft. See Figure 29. Install the snap ring into bearing housing to retain ball bearing. This snap ring has a tapered edge to fit tapered groove in bearing housing. The tapered edge is located away from the ball bearing.

AS, AK, AL: Install the ball bearing into the bearing housing. Install the lip seal in the bearing housing end cap. The lip should face towards the end of the shaft. Put the bearing spacer collar in the lip seal and install in the bearing housing and tighten the set screws securely. See Figure 30.

16. Insert a brass bar or piece of hardwood through the port opening between the rotor teeth to keep the shaft from turning.

17. Start the thrust bearing assembly into casing. Turn by hand until tight. This forces the rotor against the head. Replace and tighten the locknut or shaft.

18. Remove the brass bar or hardwood from port opening.

19. Adjust pump end clearance, refer to “Thrust Bearing Adjustment.”

DANGER

BEFORE STARTING PUMP, ENSURE THAT ALL DRIVE EQUIPMENT GUARDS ARE IN PLACE. FAILURE TO PROPERLY MOUNT GUARDS MAY RESULT IN SERIOUS INJURY OR DEATH.

THRUST BEARING ADJUSTMENT

Loosen two screws in face of thrust-bearing assembly. See Figures 29 or 30.

If shaft cannot be rotated freely, turn thrust-bearing assembly counterclockwise until shaft can be turned easily.

1. While turning rotor shaft, rotate thrust-bearing assembly counterclockwise until noticeable drag occurs. This is zero end clearance.

2. Mark position of bearing housing with respect to the casing.

3. Rotate thrust-bearing assembly counterclockwise the distance listed below as measured on outside of bearing housing.

4. Tighten two setscrews in face of bearing housing after adjustment is made to secure thrust-bearing assembly position.

For viscosities above 2500 SSU, add additional end clearance (0.004" for GG, HJ and HL size pumps and 0.005" for AS, AK and AL size pumps).

INSTALLATION OF CARBON GRAPHITE BUSHINGS

When installing carbon graphite bushings, extreme care must be taken to prevent breaking. Carbon graphite is a brittle material and easily cracked. If cracked, the bushing will quickly disintegrate. Using a lubricant and adding a chamfer on the bushing and the mating part will help in installation. The additional precautions listed below must be followed for proper installation:

1. A press must be used for installation.
2. Be certain bushing is started straight.
3. Do not stop pressing operation until bushing is in proper position. Starting and stopping will result in a cracked bushing.
4. Check bushing for cracks after installation.
TROUBLESHOOTING THE DEMAND PUMP

DANGER

BEFORE OPENING ANY VIKING PUMP LIQUID CHAMBER (PUMPING CHAMBER, RESERVOIR, JACKET, ETC.) ENSURE:

1. THAT ANY PRESSURE IN THE CHAMBER HAS BEEN COMPLETELY VENTED THROUGH SUCTION OR DISCHARGE LINES OR OTHER APPROPRIATE OPENINGS OR CONNECTIONS.

2. THAT THE DRIVING MEANS (MOTOR, TURBINE, ENGINE, ETC.) HAS BEEN “LOCKED OUT” OR MADE NONOPERATIONAL SO THAT IT CANNOT BE STARTED WHILE WORK IS BEING DONE ON THE PUMP.

FAILURE TO FOLLOW ABOVE LISTED PRECAUTIOARY MEASURES MAY RESULT IN SERIOUS INJURY OR DEATH.

Mark valve and head before disassembly to ensure proper reassembly.

If trouble does develop, one of the first steps toward finding the difficulty is to install a vacuum gauge in the suction port and a pressure gauge in the discharge port. Readings on these gauges often will give a clue as to where to start looking for the trouble.

Vacuum Gauge—Suction Port

1. High reading would indicate:
   b. Liquid too viscous to flow through the piping.
   c. Lift too high.
   d. Line too small.

2. Low reading would indicate –
   a. Air leak in suction line.
   b. End of pipe not in liquid.
   c. Pump is worn.
   d. Pump is dry – should be primed.

3. Fluttering, jumping, or erratic reading:
   a. Liquid vaporizing.
   b. Liquid coming to pump in slugs – possibly an air leak or insufficient liquid above the end of the suction pipe.
   c. Vibrating from cavitation, misalignment, or damaged parts.

Pressure Gauge - Discharge Port

1. High reading would indicate:
   a. High viscosity and small and/or long discharge line.
   b. Gate valve partially closed.
   c. Filter plugged.
   d. Vertical head did not consider a high specific gravity liquid.
   e. Line partially plugged from buildup on inside of pipe.
   f. Liquid in pipe not up to temperature.
   g. Liquid in pipe has undergone a chemical reaction and has solidified.
   h. Relief valve set too high.

2. Low reading would indicate:
   a. Relief valve set too low
   b. Relief valve poppet not seating properly.
   c. Too much extra clearance.
   d. Pump worn.

3. Fluttering, jumping, or erratic reading:
   a. Cavitation.
   b. Liquid coming to pump in slugs.
   c. Air leak in suction line.
   d. Vibrating from misalignment or mechanical problems.

Some of the following may also help pinpoint the problem:

1. Pump does not pump.
   a. Lost its prime – air leak, low level in tank.
   b. Rotating in wrong direction.
   c. Motor does not come up to speed.
   d. Suction and discharge valves not open.
   e. Strainer clogged.
   f. Relief valve set too low, relief valve poppet stuck open.
   g. Pump worn out.
   h. Any changes in the liquid system, or operation that would help explain the trouble, e.g. new source of supply, added more lines, inexperienced operators, etc.
   i. Tighten end clearance.
   j. Head position incorrect.

2. Pump starts, then loses its prime.
   a. Low level in tank.
   b. Liquid vaporizing in the suction line.
   c. Air leaks or air pockets in the suction line; leaking air through packing or mechanical seal.
   d. Worn out.

3. Pump is noisy
   a. Pump is being starved (heavy liquid cannot get to pump fast enough). Increase suction pipe size or reduce length.
   b. Pump is cavitating (liquid vaporizing in the suction line). Increase suction pipe size or reduce length; if pump is above the liquid, raise the liquid level closer to the pump; if the liquid is above the pump, increase the head of liquid.
   c. Check alignment.
   d. May have a bent shaft or rotor tooth. Straighten or replace.
   e. May be a foreign object trying to get into the pump through the suction port.

4. Pump not up to capacity
   a. Starving or cavitating – increase suction pipe size or reduce length.
   b. Strainer partially clogged – clean.
   c. Strainer clogged.
   d. Pump worn out.
   e. Relief valve set too low or stuck open.
   f. Pump is cavitating (liquid vaporizing in the suction line). Increase suction pipe size or reduce length; if pump is above the liquid, raise the liquid level closer to the pump; if the liquid is above the pump, increase the head of liquid.
   g. Tighten end clearance.
   h. Head position incorrect.

5. Pump takes too much power.
   a. Running too fast – is correct motor speed, reducer ratio, sheave size, etc. being used.
   b. Liquid more viscous than unit sized to handle – heat the liquid, increase the pipe size, slow the pump down, or get a bigger motor.
   c. Discharge pressure higher than calculated – check with pressure gauge. Increase size or reduce length of pipe, reduce speed (capacity), or get bigger motor.
   d. Pump misaligned.
   e. Extra clearance on pumping elements may not be sufficient for operating conditions. Check parts for evidence of drag or contact in pump and increase clearance where necessary.

6. Rapid Wear.

Examination of a pump that has gradually lost its ability to deliver capacity or pressure would show a smooth wear pattern on all parts. Rapid wear shows up as heavy grooving, galling, twisting, breaking, or similar severe signs of trouble.
RECOMMENDED MAINTENANCE PROGRAM

In order to obtain maximum compressor unit performance and ensure reliable operation, a regular maintenance program should be followed (see Maintenance Schedule):

The compressor unit should be checked daily for leaks, abnormal vibration, noise, and proper operation. A log should also be maintained. Initial oil analysis and vibration analysis should be done at start-up and continued per the maintenance schedule.

Vibration analysis is recommended every 6 months to ensure that the internal components of the screw compressor are in compliance with expected vibration levels, based on the initial, full spectrum baseline performed at start-up. If the Frick PhD on-board vibration monitoring system is utilized, the 6 month vibration analysis is not required. Frick PhD provides continuous vibration monitoring that fulfills the maintenance requirement. Should the Frick PhD have an alarm or shut down event, a full spectrum vibration analysis would then be required to specifically identify the cause of the alarm or shut down.

In addition, a Frick compressor package without PhD monitoring already in operation can be retrofitted with the Frick PhD on-board vibration monitoring system to fulfill the vibration maintenance recommendation. However, it is also necessary to establish a current baseline vibration with a full spectrum analysis in order for the PhD retrofit to be compliant.

MAINTENANCE SCHEDULE

Recommended schedule for Frick screw compressor package preventive maintenance operations.

a. Check bolts, shim packs, center inserts, keys, and all bolt torques.
b. Verify tightness of bolts on suction and discharge flanges. See table below for torque requirements.
c. Units with variable speed drives - check for excess vibration and skip frequencies any time unit operating conditions change.
d. Check and torque all terminals in the processor and starter panel per the specification posted in the enclosure.
e. Check calibration of Slide Valve, Slide Stop, pressures and temperatures. Calibration should be conducted with NIST certified devices.
f. Baseline vibration analysis is required during initial commissioning. Vibration measurement must be carried out continuously to obtain optimum preventive control on bearings. If not continuously controlled, then every 6 months, more frequently if levels increase. See additional notes in "Recommended Maintenance Program" section above.
g. The filter may need to be changed more frequently based on differential pressure or as directed by oil analysis.

Figure 33 - Lubrication Schedule And Instructions

VIBRATION ANALYSIS
Periodic vibration analysis can be useful in detecting bearing wear and other mechanical failures. If vibration analysis is used as a part of your preventive maintenance program, take the following guidelines into consideration.
1. Always take vibration readings from exactly the same places, at exactly the same percent of load.
2. Use vibration readings taken from the new unit at start-up as the base line reference.
3. Evaluate vibration readings carefully as the instrument range and function used can vary. Findings can be easily misinterpreted.
4. Vibration readings can be influenced by other equipment operating in the vicinity or connected to the same piping as the unit. For additional information, request Frick® publication 070.902-IB.

OIL QUALITY and ANALYSIS
High quality refrigeration oil is necessary to ensure compressor longevity and reliability. Oil quality will rapidly deteriorate in refrigeration systems containing moisture and air or other contaminants. In order to ensure the quality of the refrigeration oil in the compressor unit.

**WARNING**
DO NOT MIX OILS of different brands, manufacturers, or types. Mixing of oils may cause excessive oil foaming, nuisance oil level cutouts, oil pressure loss, gas or oil leakage and catastrophic compressor failure.

**NOTICE**
The Frick oil charge shipped with the unit is the best suited lubricant for the conditions specified at the time of purchase. If there is any doubt due to the refrigerant, operating pressures, or temperatures, refer to Frick Oil publication 160.802-SPC for guidance.

1. Only use Frick® oil filter elements or warranty claim may be denied.
2. Participate in a regular, periodic oil analysis program to maintain oil and system integrity. Oil Analysis Kit part number: 333Q0001853.
3. Oil samples for analysis should be taken after the oil filter. A ¼" purge valve is provided between the filter and compressor.

MOTOR BEARINGS

CAUTION
Lubricate motor bearings properly before start-up. Maintain subsequent lubrication as recommended by the motor manufacturer. See Figure 33.

OPERATING LOG
The use of an operating log, as shown in this manual (see Table of Contents...FORMS), permits thorough analysis of the operation of a refrigeration system by those responsible for its maintenance and servicing. Continual recording of gauge pressures, temperatures, and other pertinent information enables the observer and serviceman to be constantly familiar with the operation of the system and to recognize immediately any deviations from normal operating conditions. It is recommended that readings be taken at least every four hours.

TROUBLESHOOTING GUIDE
Successful problem solving requires an organized approach to define the problem, identify the cause, and make the proper correction. Sometimes it is possible that two relatively obvious problems combine to provide a set of symptoms that can mislead the troubleshooter. Be aware of this possibility and avoid solving the “wrong problem”.

* LUBRICATION SCHEDULE FOR SEVERE SERVICE (VIBRATION, SHOCK AND/OR ENVIRONMENTAL EXTREME) = 1/3 OF THE ABOVE INTERVALS.
** LUBRICATION SCHEDULE FOR ROLLER BEARINGS = 1/3 OF ABOVE INTERVALS.

THE FACTORY INSTALLED, RECOMMENDED LUBRICANT IS LISTED ON THE MOTOR DATA PLATE. THIS IS A POLYUREA GREASE, AS ARE THE PRODUCTS LISTED BELOW. THE INTRODUCTION OF LUBRICANTS OF ALTERNATE CHEMICAL MAKEUP IS NOT RECOMMENDED AND WILL CAUSE MECHANICAL FAILURE WITHOUT THE COMPLETE PURGE OF THE FACTORY PRODUCT FROM THE BEARER AND RESERVOIR. WHEREVER POSSIBLE, APPLY THE POLYUREA PRODUCT.
ABNORMAL OPERATION ANALYSIS and CORRECTION

Four logical steps are required to analyze an operational problem effectively and make the necessary corrections:

1. Define the problem and its limits.
2. Identify all possible causes.
3. Test each cause until the source of the problem is found.
4. Make the necessary corrections.

The first step in effective problem solving is to define the limits of the problem. If, for example, the compressor periodically experiences high oil temperatures, do not rely on this observation alone to help identify the problem. On the basis of this information, the apparent corrective measure would appear to be a readjustment of the liquid injection system. Lowering the equalizing pressure on the thermal expansion valve would increase the refrigerant feed and the oil temperature should drop.

If the high oil temperature was the result of high suction superheat, however, and not just a matter of improper liquid injection adjustment, increasing the liquid feed could lead to other problems. Under low load conditions the liquid injection system may have a tendency to overfeed. The high suction superheat condition, moreover, may only be temporary. When system conditions return to normal, the unit's liquid injection will overfeed and oil temperature will drop. In solving the wrong problem a new problem was created.

The following list of abnormal system conditions can cause abnormal operation of the RXF compressor unit:

1. Insufficient or excessive refrigeration load.
2. Excessively high suction pressure.
3. Excessively high suction superheat.
4. Excessively high discharge pressure.
5. Inadequate refrigerant charge or low receiver level.
6. Excessively high or low temperature coolant to the oil cooler.
7. Liquid return from system (carryover).
8. Refrigerant underfeed or overfeed to evaporators.
9. Blocked tubes or plates in water-cooled oil cooler.
10. Insufficient evaporator or condenser sizing.
11. Incorrect refrigerant line sizing.
12. Improper system piping.
13. Problems in electrical service to compressor unit.
14. Air and moisture present in the system.

Make a list of all deviations from normal plant operation and normal compressor unit operation. Delete any items which do not relate to the symptom and separately list those items that might relate to the symptom. Use the list as a guide to further investigate the problem.

The second step in problem solving is to decide which items on the list are possible causes and which items are additional symptoms. High discharge temperature and high oil temperature readings may both be symptoms of a problem and not casually related. High suction superheat or a low receiver level, however, could cause both symptoms.

The third step is to identify the most likely cause and take action to correct the problem. If the symptoms are not relieved, move to the next item on the list and repeat the procedure until you have identified the cause of the problem. Once the cause has been identified and confirmed, make the necessary corrections.

PRESSURE TRANSDUCERS - TESTING

Test Procedure:
1. Shut compressor down and allow pressures to equalize.
2. Isolate suction transducer (PE-4) from unit and depressurize.
3. Measure the DC voltage of (PE-4) on connector (P6A) (terminals 2 and 3) on the analog board.
4. The voltage reading should be between 1.48 VDC and 1.72 VDC at standard atmospheric pressure (14.7 PSIA or 0 PSIG). When checking transducers at higher elevations, an allowance in the readings must be made by subtracting approximately 0.02 VDC per 1000 feet of elevation above sea level. Barometric pressure can generally be ignored but in extreme cases may be compensated for by adding/subtracting 0.002 VDC for each 0.1 inch of barometric pressure (adjusted to sea level) above/below 0 PSIG. Therefore, if (PE-4) is measured at 5000 feet elevation under relatively normal weather conditions, the output voltage should differ by 0.10 VDC to read between 1.38 VDC and 1.62 VDC.
5. Subtract 1 from the voltage.
7. This result is the absolute suction pressure (PSIA). Subtract 14.7 to obtain PSIG which the Operating display will indicate.
8. Isolate the oil pressure transducers (PE-1 & PE-2) from the package and depressurize.
9. Measure the voltage of (PE-1 & PE-2) on connector (P5A) (terminals 5 and 6) on the analog board.
10. The voltage reading should be between 1.1 VDC and 1.29 VDC at standard atmospheric pressure. (PE-1 & PE-2) and (PE-3) have a span of 500 PSI as compared to (PE-4) with a span of 200 PSI. Therefore, atmospheric pressure changes have a lesser effect which is 0.0067 VDC per 1000 feet of elevation and 0.00067 VDC per 0.1 inch Hg barometric deviation.
11. Subtract 1.2 from the voltage.
12. Multiply by 75, the result will be PSIG.
13. Since the discharge pressure (PE-3) cannot be closed off from its sensing point (code requirements), remove all transducers from atmosphere and open them to their sensing points so all transducers can equalize to separator pressure.
14. Measure the voltage of (PE-3) on connector (P5B) (terminals 5 and 6) on the analog board.
15. Test complete.

PRESSURE TRANSDUCERS REPLACEMENT

1. Shut off control power.
2. Close the applicable transducer isolation valve.

### NOTICE

To change the discharge pressure transducer (PE-3), it will be necessary to depressurize the entire compressor package. Follow "General Instructions For Replacing Compressor Unit Components" section before going to step 3.

### CABLE COLOR CODE

1. PIN 1: + SUPPLY
2. PIN 2: DC COMMON
3. PIN 3: SIGNAL
4. CASE GND

### TRANSDUCER CONNECTION

- **Suction Pressure**: PE-4
- **Discharge Pressure**: PE-3
- **Oil Pressure**: PE-1 & PE-2

5. Unscrew the transducer using a wrench on the metal hex at the base of the transducer. **DO NOT ATTEMPT TO LOOSEN OR TIGHTEN TRANSDUCERS BY THEIR TOP CASING.**

6. Install new transducer, reconnect DIN connector, and retighten DIN connector screw.

7. Recalibrate.

### NOTICE

If replacing older hard-wired transducer, cut cable at back of old transducer and rewire to the Danfoss unit.

8. Reopen the transducer isolation valve or compressor package isolation valves.

9. Turn on control power.
SLIDE VALVE TRANSMITTER REPLACEMENT - SLIDE STOP

The Slide Valve Transmitter (Figure 35) is located on the right side of the compressor (facing shaft) at the inlet end.

The linear transmitter with hermetic enclosure is based on the inductive measuring principle. It features removable electronics (from the sensor well) eliminating the need to evacuate the compressor for replacement. This type of transmitter is dedicated to volume ratio control and has no user adjustments.

1. Shut off control power.
2. Remove DIN connector plug from transmitter.
3. Loosen set screws.
4. Remove transmitter unit.
5. Install new transmitter unit.
6. Tighten set screws.
7. Apply DIN connector plug to transmitter.
8. Turn on control power.

NOTICE
For calibration of the Slide Valve unit, refer to the Analog Calibration instructions in publication 090.040-O.

Figure 35 - Slide Valve Transmitter

TEMPERATURE SENSOR REPLACEMENT

The Oil Level Transmitter is located on the front of the separator near the bottom/center. See Figure 37.

The linear transmitter with hermetic enclosure is based on the capacitive measuring principle. It features removable electronics (from the sensor well) eliminating the need to evacuate the compressor for replacement. This transmitter is dedicated to oil level control and has no user adjustments.

CAUTION
If it is necessary to replace the well, the separator must be purged and the oil drained. Refer to the section "CHANGING OIL."

1. Shut off control power.
2. Remove DIN connector plug from transmitter.
3. Loosen set screws.
4. Remove transmitter unit.
5. Install new transmitter unit.
6. Tighten set screws.
7. Apply DIN connector plug to transmitter.
8. Turn on control power.

NOTICE
For calibration instructions, refer to Quantum™HD Operator's Manual 090.040-O.

Figure 37 - Oil Level Transmitter

TEMPERATURE and/or PRESSURE ADJUSTMENT

All temperature and pressure sensors are factory set. If calibration is required, refer to Analog Calibration for temperature or pressure in QUANTUM™HD publication 090.040-O.

BARE COMPRESSOR MOUNTING

Refer to publication 070.660-SM.

SAE STRAIGHT THREAD O-RING FITTINGS - ASSEMBLY PROCEDURE FOR RXF 58 - 101

When performing maintenance or replacing the compressor, the hydraulic tubing may need to be removed and re-installed. The following procedure outlines the proper installation of SAE straight thread fittings to SAE straight thread ports.

The male and female ends of SAE straight thread O-ring ports have UN/UNF straight threads. An elastomeric O-ring is fitted to the male end. On assembly, the O-ring is firmly sandwiched between the angular sealing surface of the female port and the shoulder of the male end. Sealing is thus affected and maintained by the O-ring compression which results from the clamping force generated by the tightening action. The straight threads do not offer sealing action; they provide the resistance (holding power) for service pressure.

1. Inspect components to ensure that male and female port threads and sealing surfaces are free of burrs, nicks and scratches or any foreign material.
2. If the O-ring is not pre-installed to the fitting on the male end, install the proper size O-ring.
3. Lubricate the O-ring with a light coating of system oil or petroleum jelly.
4. Screw the fitting into the female port until the hex flat contacts the port face. Light wrenching may be necessary.
5. Tighten to the appropriate torque value shown in the Assembly Torque Table.

WIRING HARNESS - AC to Heaters and Valves (External)

WIRING HARNESS - AC Conduit - Quantum to DBS Panel
PROPER INSTALLATION OF ELECTRONIC EQUIPMENT IN AN INDUSTRIAL ENVIRONMENT

In today’s refrigeration plants, electronic controls have found their way into almost every aspect of refrigeration control. Electronic controls have brought to the industry more precise control, improved energy savings, and operator conveniences. Electronic control devices have revolutionized the way refrigeration plants operate today.

The earlier relay systems were virtually immune to radio frequency interference (RFI), electromagnetic interference (EMI), and ground loop currents. Therefore installation and wiring were of little consequence and the wiring job consisted of hooking up the point-to-point wiring and sizing the wire properly. In an electronic system, improper installation will cause problems that may outweigh the benefits of electronic control. Electronic equipment is susceptible to RFI, EMI, and ground loop currents which can cause equipment shutdowns, processor memory and program loss, as well as erratic behavior and false readings. Manufacturers of industrial electronic equipment take into consideration the effects of RFI, EMI, and ground loop currents and incorporate protection of the electronics in their designs. However, these design considerations do not make the equipment immune, so manufacturers require that certain installation precautions be taken to protect the electronics from these effects. All electronic equipment must be viewed as sensitive instrumentation and therefore requires careful attention to installation procedures. These procedures are well known to instrumentation, networking, and other professions but may not be followed by general electricians.

There are a few basic practices that if followed, will minimize the potential for problems resulting from RFI, EMI and/or ground loop currents. The National Electric Code (NEC) is a guideline for safe wiring practices, but it does not necessarily deal with procedures used for electronic control installation. Use the following procedures for electronic equipment installation. These procedures do not override any rules by the NEC, but are to be used in conjunction with the NEC code and any other applicable codes.

With exclusion of the three phase wire sizing, Frick drawing 649D4743 should be used as a reference for properly sizing control wires and other wiring specifications.

Throughout this document the term Electronic Control Panel is used to refer to the microprocessor mounted on the compressor package or a Central Control System panel.

**NOTICE**

It is very important to read the installation instructions thoroughly before beginning the project. Make sure you have drawings and instructions with your equipment. If not, call the manufacturer and request the proper instructions and drawings. Every manufacturer of electronic equipment should have a knowledgeable staff, willing to answer your questions or provide additional information. Following correct wiring procedures will ensure proper installation and consequently, proper operation of your electronic equipment.

**WIRE SIZING**

Control power supply wires should be sized one size larger than required for amperage draw to reduce instantaneous voltage dips caused by large loads such as heaters, contactors, and solenoids. These sudden dips in voltage can cause the electronic control panel, whether it is a micropro-

---

**VOLTAGE SOURCE**

Selecting the voltage source is extremely important for proper operation of electronic equipment in an industrial environment. Standard procedure for electronic instrumentation is to provide a clean, isolated, separate-source voltage in order to prevent EMI (from other equipment in the plant) from interfering with the operation of the electronic equipment. Connecting electronic equipment to a breaker panel (also known as lighting panels or utility panels) subjects the electronic equipment to noise generated by other devices connected to the breaker panel. This noise is known as electromagnetic interference (EMI). EMI flows on the wires that are common to a circuit. EMI cannot travel easily through transformers and therefore can be isolated from selected circuits. Use a control power transformer of the proper VA rating, usually provided in the compressor drive motor starter, to isolate the electronic control panel from other equipment in the plant that generate EMI. See Figure 38.
GROUNDING

Grounding is the most important factor for successful operation and is typically the most overlooked. The NEC states that control equipment may be grounded by using the rigid conduit as a conductor. This worked for the earlier relay systems, but it is in no way acceptable for electronic control equipment. Conduit is made of steel and is a poor conductor relative to an insulated stranded copper wire. Electronic equipment reacts to very small currents and must have a proper ground in order to operate properly; therefore, stranded copper grounds are required for proper operation.

For proper operation, the control power ground circuit must be a single continuous circuit of the proper sized insulated stranded conductor, from the electronic control panel to the plant supply transformer (Figure 39). Driving a ground stake at the electronic control may also cause additional problems since other equipment in the plant on the same circuits may ground themselves to the ground stake causing large ground flow at the electronic control panel. Also, running multiple ground conductors into the electronic control panel from various locations can create multiple potentials resulting in ground loop currents. A single ground wire (10 AWG or 8 AWG) from the electronic control panel, that is bonded to the control power neutral at the secondary side of the control power transformer in the starter and then to the 3-phase ground point, will yield the best results.

NEC size ratings are for safety purposes and not necessarily for adequate relaying of noise (EMI) to earth ground to avoid possible interference with sensitive equipment. Therefore sizing this conductor 1 – 2 sizes larger than required by code will provide better transfer of this noise.

Frick requirements for the ground conductor are:
- Stranded Copper
- Insulated
- One size larger than NEC requirements for conventional starters
- Two sizes larger than NEC requirements for VFD starters
- Conduit must be grounded at each end
- This circuit must be complete from the motor to the starter continuing in a seamless manner back to the plant supply transformer (power source).

For Direct Coupled, Package Mounted Starters, the ground between the motor and the starter may need to be made externally (Figure 40). The connection on the starter end must be on the starter side of the vibration isolators. Be certain the connection is metal to metal. Paint may need to be removed to ensure a proper conductive circuit. The use of counter-sunk star washers at the point of connection at each end will maximize metal to metal contact.

VFD APPLICATIONS

The primary ground conductor that accompanies the three-phase supply must be stranded copper, insulated and two sizes larger than the minimum required by the NEC or any other applicable codes. This is necessary due to the increased generation of EMI which is a characteristic of a VFD output to the motor when compared to a conventional starter.

For VFD applications, isolation of the control power, analog devices, and communications ground from the 3-phase ground within the starter and the electronic control panel may be necessary. This is due to the higher noise (RFI/EMI) levels generated between the VFD output and the motor, relative to a conventional starter. If these grounds are left coupled by a common back-plate in the starter/drive, this noise can be direct coupled to the control power, analog device, and communications grounding and may cause unexplained behavior and possible damage to components.
To install correctly, run a separate, properly sized (10 or 8 AWG typically) insulated ground along with and taken to ground with, the 3-phase ground at the 3-phase supply transformer (plant). This will require that the 3-phase ground and the control power ground be electrically isolated except for the connection at the plant supply transformer.

This style of grounding should steer the noise (EMI/RFI) to earth ground, reducing the potential for it to affect the sensitive equipment, which could occur if the grounds were left coupled.

**CONDUIT**

All national and local codes must be followed for conduit with regard to materials, spacing and grounding. In addition, Johnson Controls-Frick requirements must be followed where they exceed or match national or local codes. Conversely, there is no allowance for any practices that are substandard to what is required by national or local codes.

Johnson Controls-Frick conduit requirements:

- For variable frequency drives (VFDs) of any type, threaded metallic or threaded PVC-coated metallic is required for both the power feed (line side) from the source and between the VFD output and the motor (load side).
- PVC conduit is acceptable only when VFD rated cable of the proper conductor size and ground is used. This applies to both the line side and load side of the drive. When VFD rated cable is not used, threaded metallic or threaded PVC-coated metallic must be used.
- When threaded metallic or threaded PVC-coated metallic is used, it must be grounded at both ends.
- When not required to be in metal or other material by national or local codes, conduits for the power feed (3-phase) of constant speed starters may be PVC.
- When not required to be in metal or other material by national or local codes, conduits between a constant speed starter and the motor (3-phase) may be PVC.
- Any unshielded control voltage, signal, analog, or communication wiring that does not maintain 12 inches of separation from any 3-phase conductors for every 33 feet (10 meters) of parallel run must be in metal conduit which will be grounded.

Separation: (0–33 feet, 0–10 meters – 12 inches, 0.3 meters), (33–66 feet, 10–20 meters – 24 inches, 0.6 meters)

- Since PVC conduit does absolutely nothing to protect lower voltage lines from the magnetic field effects of higher voltage conductors, running either the lower or the higher voltage lines in PVC, does not reduce these requirements on separation. Only running in metal conduit can relieve these requirements.
- Due to the level of EMI that can be induced onto lower voltage lines when running multiple feeders in a trench, control power, communications, analog, or signal wiring cannot be run in trenches that house multiple conduits.

**WIRING PRACTICES**

Do not mix wires of different voltages in the same conduit. An example of this would be the installation of a screw compressor package where the motor voltage is 480 volts and the electronic control panel power is 120 volts. The 480 volt circuit must be run from the motor starter to the motor in its own conduit. The 120 volt circuit must be run from the motor starter control transformer to the electronic control panel in its own separate conduit. If the two circuits are run in the same conduit, transients on the 480 volt circuit will be induced onto the 120 volt circuit causing functional problems with the electronic control panel. Metallic dividers must be used in wire way systems (conduit trays) to separate unlike voltages. The same rule applies for 120 volt wires and 220 volt wires. Also, never run low voltage wires for DC analog devices or serial communications in the same conduit with any AC wiring including 120 volt wires. See Figure 41.

Figure 41

Never run any wires through an electronic control panel that do not relate to the function of the panel. Electronic control panels should never be used as a junction box. These wires may be carrying large transients that will interfere with the operation of the control panel. An extreme example of this would be to run 480 volts from the starter through the electronic control panel to an oil pump motor.

When running conduit to the electronic control panel, use the access holes (knockouts) provided by the manufacturer. These holes are strategically placed so that the field wiring does not interfere with the electronics in the panel. Never allow field wiring to come in close proximity with the controller boards since this will almost always cause problems.
Do not drill into an electronic control panel to locate conduit connections. You are probably not entering the panel where the manufacturer would like you to since most manufacturers recommend or provide prepunched conduit connections. You may also be negating the NEMA rating of the enclosure. Drilling can cause metal filings to land on the electronics and create a short circuit when powered is applied. If you must drill the panel, take the following precautions:

- First, call the panel manufacturer before drilling into the panel to be sure you are entering the panel at the right place.
- Take measures to avoid ESD (electrostatic discharge) to the electronics as you prep the inside of the Electronic control panel. This can be done by employing an antistatic wrist band and mat connected to ground.
- Cover the electronics with plastic and secure it with masking or electrical tape.
- Place masking tape or duct tape on the inside of the panel where you are going to drill. The tape will catch most of the filings.
- Clean all of the remaining filings from the panel before removing the protective plastic.

When routing conduit to the top of an electronic control panel, condensation must be taken into consideration. Water can condense in the conduit and run into the panel causing catastrophic failure. Route the conduit to the sides or bottom of the panel and use a conduit drain. If the conduit must be routed to the top of the panel, use a sealable conduit fitting which is poured with a sealer after the wires have been pulled, terminated, and the control functions have been checked. A conduit entering the top of the enclosure must have a NEMA-4 hub type fitting between the conduit and the enclosure so that if water gets on top of the enclosure it cannot run in between the conduit and the enclosure. This is extremely important in outdoor applications.

**NOTICE**

It is simply NEVER a good practice to enter through the top of an electronic control panel or starter panel that does not already have knockouts provided. If knockouts are not provided for this purpose it is obvious this is not recommended and could VOID WARRANTY.

Never add relays, starters, timers, transformers, etc. inside an electronic control panel without first contacting the manufacturer. Contact arcing and EMI emitted from these devices can interfere with the electronics. Relays and timers are routinely added to electronic control panels by the manufacturer, but the manufacturer knows the acceptable device types and proper placement in the panel that will keep interference to a minimum. If you need to add these devices, contact the manufacturer for the proper device types and placement.

Never run refrigerant tubing inside an electronic control panel. If the refrigerant is ammonia, a leak will totally destroy the electronics.

If the electronic control panel has a starter built into the same panel, be sure to run the higher voltage wires where indicated by the manufacturer. EMI from the wires can interfere with the electronics if run too close to the circuitry.

Never daisy-chain or parallel-connect power or ground wires to electronic control panels. Each electronic control panel must have its own control power supply and ground wires back to the power source (Plant Transformer). Multiple electronic control panels on the same power wires create current surges in the supply wires, which may cause controller malfunctions. Daisy-chaining ground wires, taking them to ground at each device, allows ground loop currents to flow between electronic control panels which also causes malfunctions. See Figure 42.
COMMUNICATIONS

The use of communications such as serial and ethernet in industrial environments are commonplace. The proper installation of these networks is as important to the proper operation of the communications as all of the preceding practices are to the equipment.

Serial communications cable needs to be of the proper gauge based on the total cable distance of the run. Daisy-chaining is the only acceptable style of running the communications cable. While Star Networks may use less cable, they more often than not cause problems and interruptions in communications, due to varying impedances over the varying lengths of cable. Ground or drain wires of the communications cable are to be tied together at each daisy-chain connection and only taken to ground in the central control system panel.

It is important to carefully consider the type of cable to be used. Just because a cable has the proper number of conductors and is shielded does not mean it is an acceptable cable. Johnson Controls–Frick recommends the use of Belden #9829 for RS-422 communications and Belden # 9841 for RS-485 up to 2000 feet (600 Meters) total cable length. Refer to Frick drawing 649D4743 for more detail.

Comm Port Protection: Surge suppression for the comm ports may not be the best method, since suppression is required to divert excess voltage/current to ground. Therefore, the success of these devices is dependent on a good ground (covered earlier in this section). This excess energy can be quite high and without a proper ground, it will access the port and damage it.

Isolation or Optical Isolation is the preferred comm port protection method. With optical isolation, there is no continuity between the communications cable and the comm port. There is no dependence on the quality of the ground. Be sure to know what the voltage isolation value of the optical isolator is before selecting it. These may range from 500 to 4000 Volts.

Frick Optical Isolation Kits are offered under part number 639C0133G01. One kit is required per comm port.

NOTICE

It is very important to read the installation instructions thoroughly before beginning the project. Make sure you have drawings and instructions for the equipment being installed. If not, call the manufacturer to receive the proper instructions and drawings. Every manufacturer of electronic equipment should have a knowledgeable staff, willing to answer your questions or provide additional information. Following correct wiring procedures will ensure proper installation and consequently, proper operation of your electronic equipment.

RXF ROTARY SCREW COMPRESSOR UNITS
FORMS
070.410-IOM (NOV 14) Page 57

READ THIS FIRST: COMPRESSOR PRESTART CHECKLIST

The following items MUST be checked and completed by the installer prior to the arrival of the Frick Field Service Supervisor. Details on the checklist can be found in this manual. Certain items on this checklist will be reverified by the Frick Field Service Supervisor prior to the actual start-up.

Mechanical Checks

Package installed according to Frick publication 070.210-IB, Screw Compressor Foundations.
- Confirm that motor disconnect is open
- Isolate suction pressure transducer
- Pressure test and leak check unit
- Evacuate unit
- Remove compressor drive coupling guard
- Remove coupling center and DO NOT reinstall
  (motor rotation must be checked without center)
- Check for correct position of all hand, stop, and check valves PRIOR to charging unit with OIL or REFRIGERANT
- Charge unit with correct type and quantity of oil
- Lubricate electric drive motor bearings PRIOR to checking motor rotation
- Check oil pump alignment (if applicable)
- Check for correct economizer piping (if applicable)
- Check separate source of liquid refrigerant supply (if applicable, liquid injection oil cooling)
- Check water supply for water-cooled oil cooler (if applicable, water cooled oil cooling)
- Check thermosyphon receiver refrigerant level (if applicable, thermosyphon oil cooling)
- Check for PROPER PIPE SUPPORTS and correct foundation
- Check to ensure ALL piping INCLUDING RELIEF VALVES is completed

Electrical Checks

Package installed according to Frick publication 090.400-SB, Proper Installation of Electrical Equipment In An Industrial Environment.
- Confirm that main disconnect to motor starter and micro is open
- Confirm that electrical contractor has seen this sheet, ALL PERTINENT WIRING information, and drawings
- Confirm proper power supply to the starter package
- Confirm proper motor protection (breaker sizing)
- Confirm that all wiring used is stranded copper and is 14 AWG or larger (sized properly)
- Confirm all 120 volt control wiring is run in a separate conduit from all high voltage wiring
- Confirm all 120 volt control wiring is run in a separate conduit from oil pump and compressor motor wiring
- Confirm no high voltage wiring enters the micro panel at any point
- Check current transformer for correct sizing and installation
- Check all point-to-point wiring between the micro and motor starter
- Confirm all interconnections between micro, motor starter, and the system are made and are correct
- Ensure all electrical panels are free from installation debris, METAL PARTICLES, and moisture

After the above items have been checked and verified:
- Close the main disconnect from the main power supply to the motor starter
- Close the motor starter disconnect to energize the micro
- Manually energize oil pump and check oil pump motor rotation
- Leave micro energized to ensure oil heaters are on and oil temperature is correct for start-up
- DO NOT energize compressor drive motor! This should only be done by authorized Factory Field Service Technicians.

Summary: The Frick Field Service Supervisor should arrive to find the above items completed. He should find an uncoupled compressor drive unit (to verify motor rotation and alignment) and energized oil heaters with the oil at the proper standby temperatures. Full compliance with the above items will contribute to a quick, efficient and smooth start-up.

The Start-up Supervisor will:

1. Verify position of all valves
2. Verify all wiring connections
3. Verify compressor motor rotation
4. Verify oil pump motor rotation
5. Verify the % of FLA on the micro display
6. Verify and finalize alignment (if applicable)
7. Calibrate slide valve and slide stop
8. Calibrate temperature and pressure readings
9. Correct any problem in the package
10. Instruct operation personnel

NOTE: Customer connections are to be made per the electrical diagram for the motor starter listed under the installation section and per the wiring diagram listed under the maintenance section of the IOM.

Please complete and sign this form & fax to 717-762-8624 as confirmation of completion.
